MACKENZIE VALLEY PIPELINE INQUIRY

IN THE MATTER OF AN APPLICATION BY CANADIAN ARCTIC GAS
PIPELINE LIMITED FOR A RIGHT-OF-WAY THAT MIGHT BE
GRANTED ACROSS CROWN LANDS WITHIN THE YUKON TERRITORY
AND THE NORTHWEST TERRITORIES FOR THE PURPOSE OF THE
PROPOSED MACKENZIE VALLEY PIPELINE

and

IN THE MATTER OF THE SOCIAL, ENVIRONMENTAL AND ECONOMIC
IMPACT REGIONALLY OF THE CONSTRUCTION, OPERATION AND
SUBSEQUENT ABANDONMENT OF THE ABOVE PROPOSED PIPELINE

(Before the Hon. Mr. Justice T.R. Berger, Commissioner)

Yellowknife, N.W.T.

March 3, 1975.

PROCEEDINGS AT INQUIRY

VOLUME IX

APPEARANCES:

Mr. Ian G. Scott,
Mr. Stephen T. Goudge,
Mr. Alick Ryder and
Mr. Ian Roland

for Mackenzie Valley
Pipeline Enquiry;

Mr. Pierre Genest, Q.C.
Mr. Jack Marshall,
Mr. Darryl Carter, and
Mr. John Steeves

for Canadian Arctic Gas
Pipeline Limited;

Mr. Reginald Gibbs and
Mr. Alan Hollingworth

for Foothills Pipelines
Ltd.;

Mr. Russell Anthony,
Prof. Alastair Lucas &
Dr. Andrew Thompson

for Canadian Arctic
Resources Committee;

Mr. Glen W. Bell and
Mr. Gerry Sutton

for Northwest Territories
Indian Brotherhood and
Metis Association of the
Northwest Territories;

Mr. John U. Bayly

for Inuit Tapirisat of
Canada and the
Committee for Original
Peoples' Entitlement;

Mr. Ron Veale and
Mr. Allan Luke

for Yukon Native Brother-
hood;

Mr. Carson H. Templeton

for Environment Protection
Board;

Mr. Murray Sigler

for Northwest Territories
Association of Municipali-
ties and
Northwest Territories
Chamber of Commerce

Yellowknife, N.W.T.,

March 3, 1975.

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

THE CHAIRMAN: Ladies and gentlemen, this enquiry has been established to consider what the impact will be of the pipeline that Arctic Gas wants to build to bring natural gas from the Arctic to southern markets.

We are today beginning the formal hearings of the enquiry. In these formal hearings we will be examining the multitude of studies and reports that have been prepared by the government, by the industry, and by the participants. There will be the fullest opportunity for the ventilation of the evidence, the opinions, and the arguments of all concerned.

But I want to make it clear that the enquiry will not be limited to these formal hearings. We will be holding hearings in every community in the Mackenzie Valley likely to be affected by the pipeline. At the community hearings there will be an opportunity for the people who live in the valley to tell me what they think, and to say what they want to say.

To enable the people in the cities and towns, the settlements and villages in the Mackenzie Valley, to know what is being said here in Yellowknife at the formal hearings, summaries of the evidence given will be broadcast on a regular basis to all of the communities, in English and the native languages.

1 The proposed pipeline is not to
2 be considered in isolation. The Pipeline Guidelines
3 laid down by the Government of Canada require an examin-
4 ation of the proposed pipeline in the context of the
5 development of a Mackenzie Valley Transportation Corri-
6 dor.

7 So we are embarked on a cons-
8 ideration of the future of a great river valley and its
9 people. I want the people who make this valley their
10 home to have a chance to tell me what they would say to
11 the Government of Canada if they could tell them what
12 was in their minds. Then it will be my task to report
13 to the Minister of Indian Affairs and Northern Develop-
14 ment regarding the social, economic and environmental
15 impact of the project here in the north, and to recom-
16 mend the terms and conditions that should be imposed
17 with respect to any right-of-way that may be granted
18 for the pipeline.

19 It will be for the Minister
20 and his colleagues -- for those who govern our country
21 -- ultimately to determine whether there should be a
22 pipeline, and the terms and conditions that should be
23 imposed with respect to any right-of-way.

24 Mr. Scott?

25 MR. SCOTT: I would like at
26 the beginning to review some of the steps that have
27 been taken to prepare for this enquiry, and the plan
28 that we contemplate will be followed as we proceed
29 with the formal and community hearings. As you will know,
30 sir, of course, late last year and in the spring there

1 were two full preliminary public hearings at which the
2 participants and the public were invited to make recom-
3 mendations to you, as to the nature of discovery before
4 hearing, and as to the nature that the formal and
5 community hearings themselves should take.

6 Following those full public
7 hearings, your preliminary rulings were made, the last
8 of which was made in the autumn of last year.

9 Since that time and in complia-
10 nce with your rulings, each major participant has filed
11 a list of reports and studies within his possession or
12 power and inspection of those reports and studies by
13 other participants and interested persons has been had
14 or is at least well under way. The object of that
15 exercise, of course, is to assure that before hearing
16 and before evidence there will be full disclosure by
17 everybody of all technical and other relevant material
18 in the possession of the parties. In compliance with
19 the duty imposed upon me, I have filed with the Commis-
20 sion a list of reports and studies in the possession of the
21 Government of Canada which are also, as noted in the
22 preamble to that list, available for inspection by all
23 participants.

24 A Committee has been establish-
25 ed respecting community hearings under the chairmanship
26 of Professor Jackson of the Commission staff, and it is
27 made up of all interested parties including the North-
28 west Territories Association of Municipalities, Arctic
29 Gas, and representatives of the organizations of
30 native peoples, and is presently at work planning the

1 format and timing of hearings -- community hearings --
2 to be held in all the communities and settlements of
3 the valley and the delta.

4 The Government of Canada
5 Assessment Group has in addition filed its report and
6 has made to the applicant its requests for supplementary
7 information.

1 Arctic Gas has in turn filed
2 its response to that request. All of that material
3 is now or will be available for inspection in the
4 office of the Commission in the Resources Building
5 at Yellowknife.

6 Mr. Commissioner, the overview
7 directed by you in your first preliminary rulings
8 will begin tomorrow. We will bring evidence before
9 you that is designed to provide a backdrop against
10 which the position of the applicant and the intervenors
11 and the interested persons in the territories may be
12 seen as the hearings progress.

13 The overview evidence is
14 designed to include, in a general way, such matters
15 as the history, culture, and economy of the northern
16 peoples, the geography and theological history of the
17 MacKenzie Valley, the delta and the Yukon, the climate,
18 the geotechnical aspects of northern construction,
19 terrain types, including permafrost and resources,
20 renewable or non-renewable.

21 After the overview hearing is
22 completed, that is in approximately one week's time,
23 we will commence the formal hearings of the inquiry
24 in which we will examine in four, perhaps more, but
25 certainly four phases, the application of Arctic GAs.
26 The division of those phases and their general ambit
27 has been set out in your preliminary rulings.

28 Phase one will deal with the
29 engineering and the construction of the proposed
30 pipeline and at these hearings there will be evidence

1 dealing with such matters as the size of the pipeline,
2 its location, the timing of construction, the compo-
3 sition and deployment of construction crews, the
4 construction of compressor stations and matters of
5 that kind.

6 Following upon phase one will
7 come phase two in which we will consider the impact of
8 a pipeline and the MacKenzie corridor development on
9 the physical environment. This phase of the hearings
10 will include the impact on the land, the air, and the
11 water and will cover in detail such things as the
12 effect of the pipeline on permafrost, river crossings,
13 slope stability, gravel, and other bore hole locations
14 and matters of that general description.

15 Phase three will deal with the
16 impact of the pipeline on the living environment and
17 in this phase you will be asked, sir, to give
18 detailed consideration to the impact of the proposed
19 pipeline on plant and animal life, including wildlife,
20 mammals and fishes.

21 In phase four we will consider
22 the impact of the pipeline on the human environment and
23 here of course you will hear much evidence that will
24 deal with the anticipated impact of the pipeline on
25 the social and economic life of this community.

26 Today, the opening day, is
27 reserved for opening statements by the major partici-
28 pants. Before coming to that I want to emphasize as
29 firmly as I can that this is designed to be an
30 open inquiry and there will be opportunity for

1 every person, whether represented by a lawyer or not
2 to participate by way of asking questions or making
3 statements and if you wish, any of you, assistance
4 in doing that, please let Mr. Waddell of the Commission
5 Staff know, or let me know and arrangements will be
6 made for a convenient time when you can present your
7 position as an individual or present your question
8 to the panel of witnesses that may be giving evidence.

9 The purpose of the opening
10 statements today derives from the fact that there are
11 a number of participants who have indicated to the
12 Commission that they propose to be a continuing
13 presence in these inquiries, in this inquiry, and
14 are prepared to take a firm position on all the major
15 issues that it is anticipated will come before you.

16 As a result of that fact, it
17 was thought to be orderly and desirable to permit them
18 to make a short opening statement each in which it is
19 anticipated they will detail their approach to the
20 issues and the case that they intend to advance before
21 you.

22 I wish to repeat an observation
23 that was made in the preliminary hearings about
24 the role of Commission Counsel. We have been
25 assigned a specific role by you, sir, under your preliminary
26 ruling. I emphasize that in addition to the
27 obligations that are cast on us there, we intend to
28 take throughout a positive and active posture in
29 these hearings to assure that every view is tested
30 and heard.

1 This is done in compliance
2 with your clear injunction that this enquiry must be
3 a full and a fair one.

4 So, sir, with some trepidation
5 we are prepared to begin. It is, I think, for all of
6 us a solemn and an important moment. The experience
7 beginning today, as you have said, sir, is unique in
8 Canadian history, and we begin with the hope that recom-
9 mendations of the enquiry will in the end be uniquely
10 useful for the people of this great valley and for the
11 people of Canada. A great judge of this Territory once
12 said that justice must be taken to every man's door,
13 and that to a marked extent has been the watchword of
14 our preparation as your counsel. The enquiry will be
15 long; it will be detailed; it will be arduous. But
16 we pledge that it will be open. The enquiry will hear
17 not only from scientists and builders and government
18 people, but it will be taken to the people by radio
19 and television and in turn the enquiry will go to the
20 people at hearings in each community.

21 Sir, it is our hope that by
22 this effort the enquiry will be a model for the plann-
23 ing of great national developments in the future.
24 I'm obliged, sir.

25 THE CHAIRMAN: Thank you, Mr.
26 Scott. Mr. Genest?

27 MR. GENEST: Mr. Commissioner,
28 I am grateful to Mr. Scott for having pronounced my
29 name correctly because -- and to you, sir -- because
30 in the last two years I've spent a considerable amount

1 of time in the north, and I have found the greatest
2 difficulty in having my name pronounced correctly.

3 I understand you, sir, suffer from somewhat the same
4 difficulty with the hard "G".

5 As you know, I represent the
6 Arctic Gas, and I thought it would be appropriate to
7 commence my opening statement by introducing to you and
8 to the participants and the public the counsel who
9 will or may be appearing on behalf of Arctic Gas from
10 time to time in these proceedings, and again give you
11 the correct pronounciaton of their names.

12 I appear, together with Mr.
13 Marshall, Jack Marshall from Calgary; Mr. Darryl
14 Carter of Yellowknife, and Mr. John Steeves of Vancouver.
15 Mr. Commissioner, these may seem to some to constitute
16 an excessively large gaggle (if that is the proper word)
17 of lawyers, and I should explain why we have felt it
18 necessary to be here in such numbers.

19 As you know, before it can
20 proceed with the pipeline which is the subject matter
21 of these hearings, Arctic Gas must go through at least
22 three major hearings: the first to start is yours,
23 sir, at the conclusion of which you will be filing your
24 report to the Minister of Indian Affairs and Northern
25 Development; secondly, there will be very extensive
26 hearings before the National Energy Board of Canada for
27 a certificate of public convenience and necessity;
28 thirdly, extensive hearings will be held by the Federal
29 Power Commission in the United States in respect of
30

1 those portions of the total project which relate to the
2 United States. It now appears that all three of these
3 hearings will be at one time or another running concur-
4 rently and in many cases covering the same ground. It
5 may become necessary for us from time to time to detach
6 certain of the legal counsel to attend to those other
7 hearings. Indeed, at the present time Mr. Goldie who
8 appeared before you at the Preliminary Hearings as
9 the chief counsel for Arctic Gas, has disappeared into
10 the National Energy Board and is engaged fulltime
11 before the Energy Board in its hearings into the supply
12 and demand of natural gas in Canada. So in order to
13 provide continuity and to assure that your hearings
14 will have the assistance of well-briefed counsel on
15 the part of Arctic Gas, whose every facet is being
16 examined in these hearings, we have felt it a wise
17 precaution to brief this number of counsel.

18 Having dealt with counsel, sir,
19 I should now like to say a few words which may be re-
20 petitive to some, but which I think bear repeating to
21 describe Arctic Gas and tell you briefly what it is.

22 Canadian Arctic Gas Pipeline
23 Limited and its sister company, Canadian Arctic Gas
24 Study Limited, are companies incorporated under and
25 subject to Canadian laws. Its present sponsors include
26 a group of enterprises which have amongst them a number
27 of companies engaged in the business of exploring for
28 and producing oil and natural gas, a number of companies
29 engaged in the business of transmitting natural gas,
30 and a number of companies engaged in the business of

1 distributing and selling natural gas to the homes and
2 industry of Canada and United States.

3 Canadian interests are sub-
4 stantially represented in the group of sponsors and
5 the management of the companies is almost entirely
6 Canadian. This pipeline will, if constructed, be sub-
7 ject to National Energy Board regulations, including
8 regulation of its rate of return. It will be what is
9 called a contract carrier, that is a company involved
10 in the transmission or transportation of gas only.,
11 ready to carry gas for anyone in accordance with a
12 tariff which must be approved by the National Energy
13 Board of Canada.

1 If this project receives the
2 necessary approval, sir, and gets underway, the owners
3 of the equity, that is those who will then control
4 the company, are not necessarily going to be its present
5 sponsors. Indeed it is the intention/of the management
6 and of its sponsors to raise the majority of the
7 equity financing for this project in Canada and it
8 is expected that the majority of this equity capital,
9 the majority of the controlling votes in the share
10 capital of this company will be owned in Canada by
11 Canadians.

12 The Arctic Gas Companies
13 were brought into existence by reason of the concern of
14 its sponsors over a possible shortage of natural gas
15 facing Canada and the United States. That possibility
16 has now become a fact. Extensive studies were carried
17 out into the feasibility of making available to the
18 people of Canada the gas supplies which were thought
19 to exist in the Northwest Territories and to the
20 people of the United States, the gas found to exist on
21 the north slope of Alaska at Prudhoe Bay.

22 An amount in excess of
23 \$75,000,000 has now been spent by the sponsor groups
24 in order to carry out what I can call without
25 hesitation the most extensive and thorough preliminary
26 engineering, environmental and sociological study
27 ever given to any project anywhere. Further substan-
28 tial expenditures are budgeted and I point out that
29 all of these expenditures will be made before there is
30 any assurance at all that the project will receive

1 the necessary approvals to get it started. The studies
2 I have mentioned, sir, range from extensive engineering
3 feasibility studies to studies of the socio-economic
4 impact of the pipeline on the North and its individual
5 communities, to studies on the habitat and nature of
6 numerous species of the vegetation and wild life of the
7 North and the impact of the possible construction of
8 a pipeline upon them. They have been carried out
9 by the most highly qualified people that were available
10 to us, almost all of whom are Canadians. The full nature
11 and extent of these studies and the high qualifications
12 of the persons who carried them out will, I believe,
13 become evident as these hearings progress.

14 Having briefly reviewed the
15 identity of Arctic Gas, sir, let me now deal briefly
16 with the project that it proposes to undertake. As
17 outlined in our application, the project involves the
18 construction and operation of a large diameter natural
19 gas pipeline some 2,435 miles long and if you will
20 turn to the map which I cannot see very well from
21 over there, a little better over here, the route of
22 the line is shown.

23 One leg which you would call
24 a supply line, or a supply lateral, would commence
25 at the Yukon-Alaska border connecting there with a
26 pipeline to be constructed from the Alaskan gas
27 fields at Prudhoe Bay; the other leg, or supply line
28 would commence from the Taglu Field on the North Shore
29 of Richards Island in the Northwest Territories of
30 Canada; Another supply line will join this one from

1 the Parsons Lake area in the Northwest Territories.
2 Now, these two main legs will join into a trunk or main
3 line at Travaillant Lake -- I do not know if that is
4 the way that it is pronounced here, but that is the
5 way that it is pronounced in my language -- just south
6 of the MacKenzie Delta. This main line will then
7 proceed south down the Mackenzie Valley and then into
8 Alberta where it will split into a number of lines
9 designed to carry Canadian gas to Canadian users and
10 American gas to American users.

11 What I have just described
12 sir, is what we call in our application the "Prime
13 Route". We have also described in our application what
14 -- and that is not shown on the map on the wall --
15 what we call the interior route, which is an alternative
16 way of bringing the Alaska gas supply leg into the main
17 trunk pipeline. This is a route which will proceed
18 through the Brooks Mountain Range of Alaska, then move
19 east across the Alaska - Yukon border, through the
20 Richardson Mountains of the Northwest Territories
21 to join the Taglu supply line at the same junction point
22 as would the Prime Route, that is near Travaillant Lake.
23 This is a route which when the application was filed,
24 we found less preferable than the Prime Route but which
25 we are prepared to utilize should decisions either in
26 Canada or the United States make the Prime Route not
27 available.

28 I should also mention, sir,
29
30

1 that some weeks ago I advised the Commission and the
2 Participants that Arctic Gas had then under study a
3 further alternative route for bringing Alaska gas to
4 the main trunk line, a route called the "Cross Delta
5 Route" which instead of coming down on the west side
6 of the Mackenzie Delta would go directly across Shallow
7 Bay at the top of the Delta and join the main trunk
8 line just south of Taglu. We will shortly be filing ,
9 sir, with the Minister and with your inquiry detailed
10 information with respect to this alternative route.

1 I should like here, having
2 described the project very briefly, to correct what
3 appears to be a general misconception as to the escala-
4 tion of costs on the project. The figure of \$10 billion
5 is being mentioned quite often as the cost of the
6 Arctic Gas project, and that is not so. The original
7 cost estimated as set out in our application was \$5.7
8 billion. That is the cost of the project from the
9 Alaska border to the Canadian-United States border.
10 Our estimates of the effect of future inflation, that is the
11 inflation that will take place -- the depreciation that
12 will take place in the value of money over the life of
13 the construction of this project, has brought our
14 estimates of the total capital cost in escalated dollars
15 to \$7 billion, and not \$10 billion.

16 This, then, sir, is in the
17 briefest outline, is the nature of the project. It
18 is a project which we submit is clearly in the national
19 interest of Canada and which we also submit will bring
20 substantial benefits to the people of the north, with
21 whose well-being your enquiry is largely concerned.
22 The reason we seek to build this undertaking is that it
23 is the most economically feasible way to bring badly
24 needed Canadian gas to Canadians. This statement is
25 based on a few simple propositions:

- 26 1. Canada is faced with an imminent and serious
27 shortage of energy, in particular natural gas,
28 which will have extremely serious consequences
29 for the people of Canada if action is not taken
30 promptly to secure and transport to market new

- 1 sources of supply.
- 2 2. The United States is faced with a similar shortage.
- 3 3. There are extensive gas reserves situated in
- 4 Canada's Mackenzie Delta which are urgently needed
- 5 to alleviate the Canadian shortage.
- 6 4. Even more extensive gas reserves have been located
- 7 in the Prudhoe Bay area of Alaska, which are also
- 8 urgently needed by the United States to alleviate
- 9 their own shortages.
- 10 5. Because of the existing level of proven reserves
- 11 in the Mackenzie Delta, it is not economically
- 12 feasible to construct a pipeline for the exclusive
- 13 purpose of piping Delta frontier gas to Canadian
- 14 markets.
- 15 6. The transportation of Prudhoe Bay gas to American
- 16 markets by means other than a pipeline crossing the
- 17 territory of Canada would be far more expensive.
- 18 7. The construction of a trunk pipeline which will
- 19 carry to Canadians our own Delta gas and will
- 20 carry to the United States its own Prudhoe Bay
- 21 gas, is the only economically feasible solution
- 22 for Canada at this time.
- 23 8. Lastly, while the discovery of a great deal more
- 24 gas in the Delta would make possible a line for
- 25 Canadian gas only, at some unknown time in the fut-
- 26 ure, a joint line carrying both American and
- 27 Canadian gas will always remain the most economic
- 28 alternative.

29 In short, sir, what we believe
30 this project offers to Canada is the presently most

Mr. Commissioner,
1985-10-15-12

1 economically feasible contribution to Canada's defence
2 against the world energy crisis -- the best chance to
3 reduce substantially Canada's exposure to the vast
4 economic and financial problems which, if they are not
5 solved or alleviated, are bound to seriously affect the
6 well-being of every Canadian man, woman and child.

7 Mr. Commissioner, these are all
8 propositions the validity of which will be examined in
9 detail by the National Energy Board. The concern of
10 your enquiry relates almost entirely to the consequences
11 to the environment and people of the north, of the
12 building and operation of the project, and it is to that
13 subject that I now wish to turn.

14 Mr. Commissioner, the position
15 taken by Arctic Gas in its application and which we hope
16 to demonstrate to you and to the people of the north in
17 these hearings is that the construction and operation of
18 this pipeline, subject to proper safeguards and to
19 management responsive to the needs of the north, will be
20 of positive economic and social benefit to the people
21 of the north.

22 Notwithstanding our position,
23 that the effect of this pipeline in the north will be
24 positive, let me state at once that we do not pretend
25 and we do not allege that there will be no damage or
26 impact by this pipeline. What we do say is that any
27 environmental damage which will be caused will not be
28 lasting, that it can be alleviated to a point where
29 it will not significantly affect the northern environ-
30 ment. Again, we do not say that there will be no

1 impact on the lives of the people in the north. Some
2 of these effects will be positive and some will be
3 adverse. What we do say and what we hope to demonstrate
4 during the course of these hearings is that the positive
5 benefits of this project on the economy and life-style
6 of the peoples of the north will far outweigh any
7 negative effect.

8 Mr. Commissioner, the hard
9 fact is that without some sort of economic development,
10 this land -- this northern land, enormous, beautiful
11 and awe-inspiring as it is -- is not now supporting the
12 population of the Northwest Territories. The hard fact
13 is that many northerners whose forebearers lived off the
14 land do not want to go back to the traditional means of
15 making a livelihood. The hard fact is that at present
16 there is insufficient economic activity in the north
17 to give the opportunity for all those who seek wage
18 employment to fulfil themselves in these Territories.
19 Indeed, sir, our evidence will show that a good deal
20 of economic activity which is now taking place in the
21 Territories is there by reason of the anticipation of
22 the construction of this pipeline and that if the pro-
23 ject were not to go forward, the pace of economic
24 activity, the opportunities for job employment in the
25 north would reduce to an extent that would work great
26 hardship for a large proportion of the people now
27 residing here.

28 Our case is, sir, that the
29 north as a whole needs a sound and stable economic
30 base which will provide wage employment for those who

1 wish to seek it. Our submission is that the pipeline
2 will provide that economic base without interfering with
3 or restricting the freedom of choice of those northern-
4 ers who wish to earn their livelihood from the land.

5 In your preliminary rulings, sir,
6 you declared that the contention of the native organiza-
7 tions that no pipeline development should proceed until
8 the land claims of the native people have been settled
9 was one which they were entitled to urge upon this
10 enquiry; you stated that the native organizations should
11 indicate to this enquiry the nature and extent of their
12 claims so that, and I quote from the words of your
13 ruling:

14 "The enquiry will then be in a position to indicate
15 to the Minister what measures ought to be taken
16 to ensure that the native peoples in their
17 negotiations with the government do not find
18 themselves at any disadvantage owing to the
19 building of the pipeline, and looking to the
20 consummation of negotiations, what measures
21 ought to be taken to ensure that whatever the
22 extent of the native interests that may ultimately
23 be recognized by any settlement, it will not be
24 diminished by the construction of the pipeline
25 in the meantime."

1 Sir, your ruling then
2 properly went on to point out that the negotiation
3 of a settlement of native claims in the north was a
4 matter for the government of Canada and the native
5 people and that nothing said at this inquiry can bind
6 either side. Indeed, this inquiry is not the place
7 where these claims can or will be settled but you did
8 invite the native organizations to lay before the
9 Inquiry a statement as to the nature and extent of
10 their land claims.

11 Mr. Commissioner, Arctic
12 Gas recognises the necessity for a fair and just
13 settlement of the land claims of the native. Our
14 position is that the pipeline can indeed be built
15 without prejudice to the settlement of the native
16 land claims and following the presentation to this
17 Inquiry of the precise nature of these claims, we
18 propose to make submissions directed to that issue..

19 Basically, sir, it is a func-
20 tion of your hearings to test and examine the validity
21 of the submissions I have just been making. The
22 Order-in-Council , dated March 21, 1974, constituting
23 this inquiry provides that you are, and I quote,
24 "to inquire into and report upon the terms and condi-
25 tions that should be imposed with respect of any right
26 of way that might be granted across Crown Lands for
27 the purposes of the proposed Mackenzie Valley pipeline
28 having regard to A) the social environmental and
29 economic impact regionally of the construction opera-
30 tion and subsequent abandonment of the proposed

1 pipeline in the Yukon and the Northwest Territories
2 and B) any proposals to meet the specific environmental
3 and social concerns set out in the expanded guidelines
4 for the Northern territories."

5 The Order-in-Council has left
6 you, sir, with broad discretion as to the methods you
7 should follow in holding the inquiry authorized thereby.
8 The preliminary rulings which you have made have
9 dictated the course, scope and extent of these hearings
10 and have insured that they will be a landmark in public
11 inquiries of this sort. Every precaution has been
12 taken to enable you in your own words, and I quote:
13 "... to conduct a fair and thorough inquiry , to give
14 all those persons and organizations with an interest
15 in the proposal made by Arctic Gas a fair opportunity
16 to be heard."

17 With the co-operation of
18 the Government, substantial funds have been granted by
19 you to many of those who are here as Participants,
20 representing special interest groups and special
21 points of view to enable them to make a meaningful
22 contribution to these hearings and to brief able and
23 experienced counsel to assist them.

24 Mr. COMmissioner, we have
25 tried in making our plans for this pipeline and in
26 drafting our application to anticipate and foresee
27 to the best of our ability the various problems which
28 might occur as a result of the construction and oper-
29 ation of this project. Notwithstanding the expertise
30 of the many people who have participated with us in

1 preparation of these plans, we do not claim to be
2 the possessors of all wisdom. We believe that each
3 of the participants here can make a valuable contri-
4 bution in bringing forward the special points of
5 view, the special concerns of the people and groups that
6 they represent. Some of these we may have overlooked
7 or given insufficient importance to and as a result
8 the representations of these groups may cause you to
9 recommend beneficial changes by the imposition of
10 beneficial terms and conditions.

11 We do not look, sir, upon
12 the participants here as opponents. We rather look
13 upon all of us engaged in this inquiry as a group
14 dedicated to the search for the best method of protec-
15 ting the legitimate claims and interests of the people
16 of the north and the people of Canada.

17 Our objective, Sir, is not
18 only to try and persuade you as to which terms and
19 conditions you ought to report to the Minister
20 should be imposed in respect of our right of way but
21 it is also by full and frank disclosure to communicate
22 to the citizens of the north of Canada our sincere
23 desire that this project, which we say is essential
24 to the well being of Canada as a whole, brings to the
25 citizens of the North their proper share of the
26 benefit. We hope to be here in the North long after
27 this inquiry is over. We wish to live in the north
28 as friends and neighbours of all of the people of the
29 North and to enjoy their good will and trust and we
30 hope that these hearings will help to achieve that

1 that purpose.

2 We also confidently look to
3 you, Sir, for leadership in ensuring that these hearings
4 which will deal with complex matters and conflicting
5 points of view, do in fact fulfil their purpose.
6 We look to you to keep all of us lawyers, who are used
7 to the adversary system and I am the first to be
8 guilty of it, there are sometimes excessively fond
9 of the sound of our own voices, who look to you to
10 keep us on the track so that when the hearings are
11 completed the judgment as to how useful, how effica-
12 cious they have been, will not be that they have
13 been so cumbersome and so lengthy that
14 nobody should ever have a hearing like that again,
15 but rather, as stated by Mr. Scott, in his remarks,
16 that they will provide a model for hearings of this
17 kind in the projects of this magnitude in the future.
18 And I pledge, Sir, that Arctic Gas and myself and my
19 co-counsel will do everything in our power to assist
20 you in your formidable task.

21 Thank you very much.

22 THE CHAIRMAN: Thank you,
23 Mr. Genest. Mr. Gibbs.

24 MR. GIBBS: Mr. Commissioner,
25 My name is Reg Gibbs. I am counsel for Foothills
26 Pipeline Committee. I have with me Mr. Alan Hollingworth who
27 will also be appearing at these proceedings. It is
28 probably more in keeping with the modest ambitions of
29 Foothill Pipeline Limited that we have only two counsel
30 compared to Arctic Gas' five, but of course, we do not

1 have to be concerned with hearings in jurisdictions
2 other than in Canada.

3 Mr. Commissioner, Foothills
4 Pipelines Limited welcomes the opportunity to make
5 an opening statement to this inquiry. By way of
6 preface perhaps I should make it plain for the benefit
7 of all persons interested in the proceedings that
8 Foothills is not an applicant but is what you have
9 classified, Sir, as a participant. But to remove
10 any lingering doubt there may be, or any hope that
11 there may be in the collective executive breasts of
12 the Toronto officers of Canadian Arctic Gas, I am
13 pleased to report, Sir, that Foothills expects to
14 file its first material with the appropriate authorities
15 by the end of March, and to continue filings until that
16 material is completed by early in May.

17 That material, Mr. Commissioner,
18 will demonstrate beyond doubt that Canadian needs for
19 natural gas can be satisfied through the Maple Leaf
20 project at no greater expense in unit costs and at
21 much lesser expense by any other yardstick in comparison
22 with the Canadian Arctic Gas proposal. It is, Sir, of
23 those underlying tangible and intangible expenses in-
24 herent in the Canadian Arctic Gas project that I pro-
25 pose to address you and I am grateful to my friend Mr.
26 Genest for raising many of these points. I am sure
27 that he will forgive me if I give them slightly
28 different emphasis.

29
30

1 So Mr. Commissioner, the
2 underlying fabric in many ways, I'm sure unintentionally,
3 concealed by rhetoric and detail to this application
4 constitutes what in my submission is a threat and
5 danger, a threat and danger to the whole of the
6 Canadian people and the Canadian nation. (X)

7 It is eminently suitable, sir,
8 that the first opportunity to examine the project
9 as a whole and to deduce the intention behind it and
10 the consequences which will flow from it if it is
11 approved, should be here in the north. It is trite to
12 say, sir, that without a grant of user of Crown lands
13 Canadian Arctic Gas will have no foundation, and without
14 a foundation, sir, the project will find its proper
15 place which, in my submission, is in the history books.
16 It is appropriate, sir, before we commence the weeks
17 and the months of the details of the proposal, to look
18 at the broad outlines and recognize the project for
19 what it is and what it is not. The recognition should
20 then stay with us and be the background against which
21 the details are superimposed for examination.

22 Mr. Commissioner, let us
23 first recognize that the Canadian Arctic Gas project
24 is not designed to meet Canadian needs. I don't have,
25 sir, the Toronto sophistication, so I form my con-
26 clusions by the usual process of simple logic. I took
27 the Canadian Arctic Gas affiliated company's -- and
28 their affiliated companies statement written and verbal,
29 and did some arithmetic, sir. I found a 48-inch
30 pipeline with an economic operating capacity of 4 1/2

1 billion cubic feet running from Prudhoe Bay across
2 Yukon and the Northwest Territories to Travaillant Lake.
3 I found a 48-inch pipeline with a similar economic
4 operating capacity of 4 1/2 billion cubic feet coming
5 down from the Delta and joining the western link at
6 Travaillant Lake.

7 I added those two together, sir, and found that their
8 total capacity is 9 billion cubic feet per day.

9 I then went to the affiliate's
10 filings, Mr. Commissioner, and looked to see what was
11 happening south of the 49th Parallel, for the Canadian
12 Arctic Gas portion is just a link in this gigantic
13 system. South of the 49th Parallel, sir, I found run-
14 ning from Kingsgate south -- Kingsgate, British Colum-
15 bia -- two new 42-inch pipelines, each with an economic
16 operating capacity of 2 1/4 billion cubic feet per
17 day. When I added those two together I got 4 1/2.

18 I then went to the east and
19 found running south from Mounie, Saskatchewan, a
20 new 48-inch pipeline with a capacity of 4 1/2 billion
21 cubic feet per day, and if you add all of those
22 volumes crossing the 49th Parallel, they come to 9
23 billion cubic feet per day, the same amount that is
24 going to come together if the pipelines operate at
25 capacity, at Travaillant Lake.

26 It seemed to me a reasonable
27 conclusion that everything that came in the north must
28 go out the south. I asked the Canadian Arctic Gas
29 representative about this on the witness stand in
30 another place and he told me, sir, that that was

1 coincidence. Now I ask, should we accept that? Or
2 might we be a little skeptical and conclude that in line
3 with pipeline economics, which say that lines must be
4 operated at capacity in order to keep unit costs down,
5 that in a very short time everything which comes in at
6 the north indeed must go out the south, in other words
7 that this system, as drawn on the map, clearly and
8 demonstrably intends that Delta gas will go into export.

9 x There is another part of the
10 design and capacity scheme, sir, that begs for recogni-
11 tion, and is perhaps somewhat more pertinent to your
12 enquiry and that is this. If we go back again to the
13 north and get these two 48-inch tunnels coming together
14 at Travaillant Lake with a 9 billion cubic feet capacity,
15 we find that they run into a single 48-inch pipeline
16 with a 4 1/2 billion cubic feet capacity, and I remind
17 you, sir, that south of the 49th parallel we have
18 9 billion cubic feet capacity. I have several times
19 tried to find the logic of feeding two, or squeezing
20 two 48-inches into one. I haven't yet been rewarded
21 with an explanation. I sincerely hope, sir, at a very
22 early stage of this enquiry a rational explanation is
23 demanded. But sir, without even waiting for it, if
24 one applies again my country logic, without it being
25 obscured by engineering data, that logic tells me that
26 every effort will and must be made to achieve economies
27 of operation in the northern extremities and the southern
28 extremities; and to achieve those economies of operation
29 and operate at maximum economic capacity I forecast, sir,
30 that there will be irresistible and irrefutable arguments

1 that the main 48-inch line comes from Travaillant Lake
2 down to Carolina, Alberta, must be doubled in size.
3 Implicit therefore in a system design is that a grant
4 of user of Crown lands south of Travaillant Lake is not
5 for one 48-inch pipeline but for two.

6 Let us then, sir, turn to the
7 question of Canadian control, which my friend raised.
8 The same Canadian Arctic gas witness with whom I spoke
9 about 48-inch pipelines told me that of the 20 corpor-
10 ate sponsors which he has, only five can be genuinely
11 called Canadian. There's not much Canadian control there,
12 sir. With respect to Canadian ownership, we are told
13 by statements emanating from Toronto that the intention
14 is that there will be an opportunity for Canadians to
15 subscribe at one time it was for half the equity and
16 now I gather this morning it's for a greater amount.
17 Well, sir, that's cold comfort.

18 I grew up in an area secure
19 in the knowledge which I am sure is shared by northern-
20 ers that the road to Toronto is paved with good inten-
21 tions. Sir, that thesis of Canadian ownership cannot
22 ever be more than a good intention. My friend has
23 repeated to you this morning that in escalated costs
24 the capital expenditure for the Canadian portion of this
25 system will be something in the order of \$7 billion.

26 Traditionally utilities are
27 financed on the basis of 25% equity and 75% debt.
28 By my calculations, sir, 25% of \$7 billion is \$1.8
29 billion, and only half of that even is \$900 million.
30 Now, sir, I'm sure that even the most sanguine of the

1 Canadian Arctic Gas promoters will agree with me that
2 it is absolutely and unequivocally impossible for Can-
3 adian public subscription to reach the range of \$900
4 million for this type of new and untried project.

5 To put it in perspective, sir,
6 according to Bank of Canada statistic figures, that
7 amount of \$900 million is equal to the total equity
8 issues of common stock in Canada for the years, 1972
9 and 1973 combined. With the greatest respect, sir,
10 I submit that it is frivolous to say that 50% of the
11 equity will be raised by Canadian subscription.
12 Even if that were possible, sir, of course that would
13 not represent control. Those of us who have been
14 exposed to business activities in Canada and elsewhere
15 are familiar with many corporations where 10% of the
16 equity represents control.

17 Mr. Commissioner, let us
18 also be realistic and recognize that regardless of
19 ownership, or equity ownership, there cannot be physical
20 Canadian control. The ultimate test of control, sir,
21 is the ability to stop the flow, and I predict that
22 we will not have that ability in Canada. This flow of
23 new gas, sir, through these new pipeline systems will
24 go to markets in United States which will come to rely
25 upon that gas for supply. There will be schools and
26 hospitals and residences and businesses who depend on
27 what is carried through that new highly visible 4-foot
28 tunnel from the Arctic, and that, sir, will rapidly
29 assume the character of a very visible and indispensable
30 lifeline. It's very visible on the very map that has

1 been placed on the wall, sir. I am sure that we are
2 all sufficiently familiar with world politics to know
3 that nothing will be permitted to interfere with the
4 sustenance which that gas flow will represent.

5 Sir, Canadians do not need
6 to expose themselves to that type of trouble or
7 possible confrontation.

8 Now, sir, I invite you to
9 award another recognition and that is that this
10 use of Crown lands which is requested will, if
11 granted, represent the underpinnings for a project
12 which runs directly counter to Canadian historical

13 With one significant exception, sir, factors
14 through out our history as a nation, there has been
15 insistance that main Canadian transportation and
16 communication systems follow all-Canadian routes, with
17 only convenience connections across the United States
18 border. The examples are present for all to see.
19 The Canadian Pacific Railway. The Trans-Canada Highway.
20 The Telephone and Telegraph Systems. Trans-Canada
21 Pipeline. The Air Canada, and so on.

22 The exception, the consequences
23 are spoken of in sorrow by others more eloquent than
24 I am, is the Columbia River Treaty, and this insistance,
25 Mr. Commissioner, on all-Canadian routes has, in my
26 submission, been one of the greatest single factors
27 which has preserved the integrity and sovereignty of
28 Canada. It seems incredible to me that there would now
29 be proposed at this stage in our history that we should
30 abandon all we have learned and favor construction

1 of what has been described as the equivalent of a
2 Panama Canal across Western and Northern Canada.

3 Furthermore, sir, that we should
4 be expected willingly and gratefully to use Canadian
5 land, Canadian treasures, and Canadian talent to do this,
6 to the end that there can be sucked away to foreign
7 uses a precious Canadian resource which will be needed by
8 Canadians. To use a colloquialism, sir, who needs this
9 project? Certainly Canada does not need such a gigantic
10 system designed primarily for foreign purposes. If
11 there were no other way for a market to get that much-
12 needed gas from its own territory, there might be some
13 persuasions which could be advanced. But we know, sir,
14 that there is another means of transportation for the
15 foreign gas without taking it, mingled with Canadian
16 gas along a Canadian right-of-way.

17 I do not, sir, mean to suggest
18 that Canadian markets will not need Beaufort Basin
19 gas. On the contrary, Foothills staff and consultants
20 working with the most recent available data forecast
21 a need at the latest by 1979 and probably a year or
22 two before, but why not, sir, supply this need through
23 a simpler, more manageable, more modest, more Canadian
24 approach? Why not build at a quarter of the cost
25 a smaller line just far enough to connect with existing
26 systems in Northern Alberta and British Columbia?
27 Why not let those systems carry the gas the rest of
28 the way to market along their rights-of-way, expanding
29 as market conditions require, and using spare capacity
30 as deliverability from provincial sources decline? Why

1 not by this means preserve, not merely in intent, but
2 in actuality Canadian ownership and control throughout?
3 Why not avoid those wholly new huge border-crossing
4 pipelines with the threat they propose? Why not re-
5 strict the use of Crown lands for wholly Canadian use?
6 The carriage of Canadian gas to Canadian markets through
7 Canadian systems. By a pure coincidence, sir, that
8 is exactly what Foothills proposes with its
9 Maple Leaf project.

10 Those, Mr. Commissioner, in
11 my submission, are questions to which Canadian Arctic
12 Gas must give, at a very early stage, frank and forth-
13 right answers.

14 Throughout, Mr. Commissioner,
15 I have been speaking in my capacity as counsel for
16 Foothills Pipelines Limited, but were I addressing you
17 as an individual I would have made exactly the same
18 points; for Mr. Chairman, I am as concerned and appre-
19 hensive as a Canadian, as the northerners I have heard
20 of on the radio in recent days. With all the force
21 that I can command I urge, sir, and plead that we
22 avoid the dedication of a north-south corridor, no
23 matter how narrow, to foreign use and control in perpetuity.
24 Whatever project is approved, sir, let it not be one
25 which will physically divide our nation. Thank you.

26 THE CHAIRMAN: Thank you, Mr.
27 Gibbs. Mr. Anthony?

28 MR. ANTHONY: Mr. Commissioner,
29 before beginning the opening address on behalf of the
30

1 Canadian Arctic Resources Committee I would like to
2 introduce myself and the other counsel for the Canadian
3 Arctic Resources Committee to you. I am Russell Anthony,
4 a member of the Bars of British Columbia and the North-
5 west Territories, and have the pleasure of appearing
6 before you as counsel for the Canadian Arctic Resources
7 Committee. With me from time to time will be -- as
8 associated counsel -- will be Professor Alastair Lucas
9 of the Law School of the University of British Columbia,
10 and the Bars of Alberta; with me this morning at the
11 counsel table is the chairman of the Canadian Arctic
12 Resources Committee, Dr. Andrew Thompson.

13 Mr. Commissioner, this enquiry
14 has heard at Preliminary Hearings and will hear today
15 northern people speak about their land and heritage.
16 We will also hear representatives of southern Canada
17 share their perceptions of the north and how it relates
18 to the future of Canada as a whole. We do not intend
19 to add to their eloquence; instead, we wish to direct
20 our remarks to questions of public access, public
21 participation and public accountability.

22 Prime Minister Trudeau spoke
23 a few weeks ago in Montreal about the growing suspicion
24 with which Canadians view their political institutions.
25 He lamented the lack of trust so prevalent throughout
26 the country and seemed to imply that the fault lay
27 south of the 49th Parallel owing to Watergate and
28 related events.

29 The Prime Minister surely is
30 right to identify this growing cynicism. A review of

1 resource development decisions demonstrates, however,
2 that his own government must bear a great deal of
3 responsibility for the creation of this mistrust.

4 In the years 1968 to 1972,
5 major decisions were made for Northern Canada. Everyone
6 is familiar with the Prudhoe Bay discovery, the "Manhat-
7 tan" voyage, questions of Arctic Sovereignty, off-shore
8 drilling and the Mackenzie Highway. What is documented
9 about those events is not reassuring. What little
10 policy there existed for energy and northern development
11 was based on hopelessly inadequate information. Further-
12 more, conscious efforts were made to exclude the public.
13 Not even Parliament was informed about many of the
14 discussions that took place between industry and govern-
15 ment.

16 Fundamental principles such as
17 government impartiality and the independence of regula-
18 tory agencies were distorted by officials in the
19 development of petroleum resources in Northern Canada.
20 At the same time those federal bureaucracies consistently
21 pressed for delegation of important areas of authority
22 to themselves and then closed ranks to obstruct public
23 accountability.

24 One of the most important
25 regulatory bodies in Canada is the National Energy
26 Board. The N.E.B. is referred to as an independent
27 arms-length tribunal. However, the N.E.B. was and
28 continues to be involved in day to day consensus-build-
29 ing within the Federal Government. It has also been
30 involved from the beginning with the planning of

1 northern pipelines. Does it not breed distrust for
2 Canadians to learn that the most important regulatory
3 body in this country has been so directly involved in
4 schemes for northern development?

5 It was events such as those that
6 led to the formation of the Canadian Arctic Resources
7 Committee in June, 1971. From its earliest days C.A.R.C.
8 has stressed the theme of participation --

9 "to open a window on the north,"
10 was the way our first chairman described it. C.A.R.C.
11 does not believe that policies should be made behind
12 closed doors and then "sold" to the public, nor that
13 crucial choices affecting the future of the north should
14 be made exclusively within the confines of a bureaucracy.

15 To unravel this process, and to
16 present and explain alternative policies to the
17 public, has been viewed by C.A.R.C. as its most import-
18 ant task. We have consistently argued that new review
19 procedures are necessary if Canada is to avoid the reck-
20 less ad hocery that has characterized so much develop-
21 ment on our national estate.

22 For many, the establishment of
23 this enquiry gives promise that the era of mistrust will
24 pass. It is with optimism that we have prepared our
25 submissions to you. But what has been the response
26 of the Federal Government of this enquiry?

1 While the Government pipeline
2 application assessment group is to be commended for its
3 work, the Government itself has been evasive and un-
4 co-operative. Apart from the applicant, the Government
5 is the largest source of crucial information about
6 the proposed pipeline. As with the other participants,
7 it was requested by you, Mr. Commissioner, to provide
8 a complete list of documents relevant to this inquiry
9 by November 30, 1974. The government list was not
10 submitted until the end of January, 1975 and then only
11 after the Canadian Arctic Resources Committee
12 threatened to bring proceedings to compel production
13 of the documents.

14 Immediately upon receipt
15 of the Government list, C.A.R.C. wrote to Commission
16 Counsel requesting production of these documents. To
17 date the Government has not complied and in our opinion
18 therefore, that a proper review of Government studies
19 cannot yet be made.

20 Furthermore, the Government's
21 list is seriously deficient. First, the list of
22 documents prepared by the Government departments that
23 responded was incomplete. C.A.R.C. even with its
24 limited resources has identified many significant
25 reports in the position or power of the Government
26 and its departments that have not been revealed.

27 Secondly, the Government list
28 of documents excludes the reports of such obviously
29 important agencies as the Northern Transportation Com-
30 pany Limited and the Northern Canada Power Commission.

1 The Canadian Arctic Resources Committee has further
2 written to Commission Counsel requesting that
3 the reports that these agencies be provided to this
4 inquiry. To date the Government has not replied and
5 we are therefore launching into this inquiry without
6 the opportunity of reviewing these studies.

7 The most recent actions of
8 the Government increase our apprehensions. News-
9 paper reports of the last few days reveal that the
10 Department of the Environment was instructed and
11 apparently by Cabinet order, not to intervene in
12 these hearings. As unfortunate as that may be, it is
13 only half the story. The Canadian Arctic Resources
14 Committee has discovered that the directive to the
15 Department of the Environment scientists also ordered
16 them to discontinue the preparation of questions and
17 identification of witnesses for use by Commission Coun-
18 sel as evidence before this inquiry.

19 As a result of this order, some
20 of Canada's foremost specialists on the environment
21 in the Mackenzie region, have been silent. Except
22 for consultants to the applicant, these are the only
23 scientists who have carried out field studies on the
24 proposed pipeline as well as the environment of the
25 Mackenzie for a significant period of time. The appar-
26 ent attempt to exclude this information re-kindles
27 suspiscion in the minds of many, but the decision to
28 proceed with the pipeline has been made and that the
29 Government is not interested in co-operating with a
30 full and public inquiry.

1 major route change and a second even more critical
2 change for a crossing of the Mackenzie Delta is
3 being proposed.

4 With these changes almost
5 one third of the original route will have been changed.
6 The only conclusion to be drawn is that the application
7 is premature. Yet the applicant and others urge
8 quick approval. They argue for haste because of a
9 perceived natural gas shortage. It is our submission
10 that it is just not true that there is an imminent
11 and serious shortage of energy in Canada. It cannot
12 be taken at face value that there is even a natural
13 gas shortage in Canada. The 1970 report of the Alberta
14 Energy Resources Conservation Board and evidence
15 given before the current National Energy Board hearings
16 on natural gas supplies by both the applicant, Canadian
17 Arctic Gas, and Foothills Pipeline Limited show that
18 substantial increases can be made in deliverability of
19 gas from fields in British Columbia and Alberta. Well
20 known Canadian economists have demonstrated that even
21 using the gas supply and demand figures of Arctic
22 Gas there need not be any shortage in Canada before
23 1989. Even the applicant's own witness at the N.E.B.
24 admitted that no northern pipeline may be needed before
25 1983.

26 No credence should be given
27 at this inquiry to the alarmist views about the urgent
28 need for Delta gas, especially as the National Energy
29 Board has not completed its hearings or made its report
30 to Parliament. They might even recommend a conservation

1 program aimed at leveling off consumer demand in
2 Canada. The Honourable Donald MacDonald has told
3 Parliament that the Federal Government's recently
4 announced oil conservation program will eliminate
5 the need for twelve oil sand plants by 1990.
6 Surely then a determined conservation program for
7 gas like the recently announced program to conserve
8 oil, would stem the demand for natural gas in Canada.
9 There is no reason for quick approval. This inquiry
10 must not be deterred from its resolve to conduct a
11 full and complete investigation of all possible con-
12 sequences of the gas pipeline proposal.

13 The Canadian Arctic Resources
14 Committee does not come to these hearing for or against
15 either the idea of a Mackenzie pipeline or the Canadian
16 Arctic Gas proposal referred to you in this inquiry.
17 It is here to assist in a full and complete study of
18 the issue. It is here also to urge your inquiry to
19 make recommendations that if a pipeline is built that
20 it will be built and constructed in an environmentally
21 sound and socially acceptable way.

22 We hope as well that this
23 inquiry will serve as a model for similar resource
24 development projects in the north. Such a structure
25 should provide for detailed study and public distri-
26 bution of the significant information for consultation
27 and public review prior to approval and for an on-
28 going mechanism characterised by public accountability.

29 Environmental impact assess-
30 ment has a well known methodology. It is first

1 necessary to identify environmental consequences of
2 the proposed action in the widest sense as affecting
3 people, animal and plant life and the overall natural
4 system.

5 The next step is to classify
6 these consequences. some of them are major, some
7 are minor, some have that train of secondary effects
8 and some have synergistic or cumulative effects.
9 In most cases these effects can be tolerated if steps
10 are taken in advance to modify them. But sometimes
11 these effects are irreversible. if the environmental
12 impact falls in that category, the proper course is
13 find an alternative.

14 The Canadian Arctic Resources
15 contribution to this inquiry will be to identify these
16 environmental effects and to examine what the applicant
17 proposes to do about them. The applicant's witnesses
18 will be questioned. We will follow closely the
19 evidence given by the pipeline application assessment
20 group and by the witnesses called by Commission
21 Counsel.

22 In addition, we will have the
23 assistance of the Northern Assessment Group which
24 was established with support from this Commission to
25 provide a technical and scientific review of the appli-
26 cation for the benefit of environmental and native
27 organizations.

28 The environmental concerns
29 raised by a project of this magnitude are beyond
30 number. Frost bulb around the pipeline, pressure on

1 caribou, possible disruption of breeding and staging
2 areas of migratory birds, hazardous river crossings,
3 denuding of gravel deposits so vital for northern
4 communities and cumulative effects of thousands
5 of workers and millions of tons of equipment and
6 material.

7 Faced with this impact the
8 applicant's description of its project as effecting
9 a mere 40 square miles of land is completely un-
10 realistic. Equally unrealistic is its attempt to
11 isolate its project from the overall development of
12 the north. It is now clear that the development of
13 transportation systems for the Mackenzie Valley is
14 undergoing rapid growth and evolution. The movement
15 of large quantities of material and manpower required
16 for the continuing search for oil, gas and minerals
17 in the western Arctic and sub-arctic, has required
18 a substantial increase in barge traffic on the
19 Mackenzie River accompanied by channel modification
20 to facilitate the movement of vessels of greater
21 draft.

22 Air traffic. For transport
23 of both freight and passengers has multiplied several
24 fold. Construction of the Mackenzie Valley highway
25 was begun in 1972 and the Dempster Highway which is
26 nearing completion includes sections within the
27 Mackenzie Valley just south of the Delta. There is
28 renewed expectation that an oil pipeline may be built
29 in MacKenzie Valley to carry oil from Alaska and the
30 Delta region or eventually from the Delta region alone.

1 permitted one further comment. If approval is granted
2 for a Mackenzie Valley Pipeline, all of the benefits of
3 this enquiry will have been for naught if there is no
4 effective follow-through to ensure that the safeguards
5 recommended by this enquiry are in fact observed.

6 The final report of the
7 Environmental Protection Board underlies this fact,
8 and the Canadian Arctic Resources Committee agrees
9 with their conclusions.

10 The administrative agencies
11 required to co-ordinate the supervision of hundreds of
12 contractors and sub-contractors at work in the Delta
13 and Mackenzie Valley do not now exist. No matter how
14 many laws Parliament enacts, dealing with environmental
15 safeguards, there will always be the problem of imple-
16 mentation in a particular case. Judgements are made
17 day in and day out by company and government officials
18 in the field and in regional offices. It is the
19 cumulative effect of these decisions that constitutes
20 the real success or failure of environmental protection.

21 In the final part of C.A.R.C.'s
22 presentation, we will present our studies of the pro-
23 blems faced in implementing and enforcing safeguards,
24 together with our recommendations for new procedures
25 to regulate major development within the framework of
26 long-term planning.

27 Mr. Commissioner, these are
28 the concepts and the principles that we would ask you to
29 keep in mind during your deliberations. The task before
30 you is tremendous, and the Canadian Arctic Resources

1 Committee pledges to you and to this enquiry its co-
2 operation and assistance. The people of the north as
3 well as many in the south of Canada have placed their
4 confidence in this enquiry. Like you, Mr. Commissioner,
5 we see these hearings as more than a technical review
6 of a pipeline application. This is the forum that may
7 finally open a window to the Canadian north.

8 Thank you.

9 THE CHAIRMAN: Mr. Bell?

10 MR. BELL: Since this is the
11 first time I've had the pleasure of meeting you face
12 to face, perhaps it would be appropriate if I intro-
13 duced myself. My name is Glen Bell. I'm a member of
14 the Bars of Ontario and the Northwest Territory. I
15 will be representing the Indian Brotherhood of the
16 Northwest Territories and the Metis Association of
17 the Northwest Territories for the purposes of this
18 enquiry. With me today is Mr. Gerry Sutton, the legal
19 advisor to the Indian Brotherhood of the Northwest
20 Territories.

21 Mr. Commissioner, your duties
22 as Commissioner have already brought you north of 60
23 on several previous occasions, and you are no stranger
24 to the native people of the north. Nevertheless, on
25 behalf of the Indian Brotherhood of the Northwest
26 Territories and the Metis Association of the Northwest
27 Territories I would like to extend to you now a formal
28 but nonetheless warm welcome and to offer you our best
29 wishes for a pleasant and productive experience through-
30 out the course of the enquiry.

1 Mr. Commissioner, you yourself
2 have said that this enquiry is a study whose magnitude
3 is without precedent in the history of our country. A
4 study of this size is indeed well-justified. The pro-
5 posed pipeline development is huge and far-reaching.
6 Everything about it is enormous; its length, its
7 width, its cost, its consequences for the north, and for
8 the people of Canada. The pipeline's sponsor, Canadian
9 Arctic Gas Pipeline Limited, is a consortium of corpora-
10 tions which represents the largest agglomeration of pri-
11 vate interests ever assembled in the history of Canada.

12 There are good grounds for both
13 the existence and magnitude of this enquiry. Major
14 development such as this pipeline requires close scru-
15 tiny if we are to serve properly the public interest.
16 The Mackenzie Valley Pipeline Enquiry, independent and
17 impartial, is the ideal forum in which to assess the
18 weighty issues raised by the pipeline proposal.

19 Not only is this enquiry
20 unprecedented in its size, its very existence in the
21 north is unheard of. Rarely have the native people of
22 the north been consulted in advance of large developments
23 on their land, except in the most cursory way or after
24 it was too late for their views to have any real effect.
25 In the past the pattern has been for developments to be
26 presented on a take it or leave it basis, or as a fait
27 accompli. The natives of the north are therefore
28 pleased to have this opportunity to participate in the
29 assessment of this proposal.

30 The Metis Association and the

1 Indian Brotherhood are also pleased to see the sincere
2 attentiveness with which the Commissioner has received
3 their submissions on preliminary questions. Accordingly
4 we enter this enquiry confident that it will be not
5 only full, but fair.

6 We are especially encouraged
7 by the Commissioner's stated intention to hold hearings
8 in all the communities of the north which would be affected
9 by the building of a pipeline. The Indian Brotherhood
10 and the Metis Association, while intending to participate
11 fully at the formal hearings, view the community
12 hearings as being of the utmost importance to the
13 success of this enquiry.

14 It is in the communities of the
15 Mackenzie Valley, Mr. Commissioner, that you will hear
16 most clearly the voice of the people -- people who are
17 truly of the very land on which they live. The people
18 know that through this enquiry they will be speaking to
19 all Canadians, and they will speak from their hearts.
20 They will speak of many things, not only of the pipeline
21 but also of their lives -- the good times and the
22 bad times, their hardships and their hopes. But most of
23 all they will speak of their land -- the land which
24 sustains their bodies, the land which shapes their
25 society, the land which quickens their souls.

26 There, in the communities, the
27 people will argue their case more eloquently than could
28 any pleader. We will participate as best we can
29 in this enquiry, but our participation should not be
30 taken as a sign that we accept the basic assumptions

1 of the pipeline's proponents. Those assumptions are
2 two:

3 (1) that gas in the Canadian Arctic will soon be needed
4 in Southern Canada; and

5 (2) that this pipeline is inevitable.

6 We repeat, we do not accept
7 these two assumptions.

8 The petroleum industry is
9 claiming that we will soon be in desperate need of
10 Arctic gas in southern Canada. There is plenty of rea-
11 son for the Canadian public to be skeptical. In the first
12 place, it is in the self-interest of the petroleum
13 companies to make this claim. Furthermore, there are
14 independent experts who do not agree with the oil
15 companies. These experts say that gas from Canada's
16 Arctic will not be needed in the south until at least
17 1990.

18 The situation in the United
19 States may be different. That country may or may not be
20 in need of gas from the north shore of Alaska; we are
21 not in a position to say. What we can say, however,
22 is that American energy needs do not justify a trans-
23 Canadian pipeline. Indeed, the United States is now
24 considering a trans-Alaska gas pipeline, known as the
25 El Paso line.

26 Nor can we accept the assump-
27 tion that the Mackenzie Valley Pipeline is the unstop-
28 pable juggernaut which its sponsors would have us
29 believe. Canadian Arctic Gas spokesmen were recently
30 quoted in the press as saying that the latest estimates

1 of the cost of the pipeline are \$10 billion. This is
2 up from an estimate last fall of \$6 billion, and
3 construction has not yet begun. Mr. Genest informed
4 us today that the estimate should be closer to \$7
5 billion.

6 Well, in spite of this con-
7 fusion , it is clear that if other large energy develop-
8 ments provide any indication, further cost increases
9 seem probable. An example is the Syncrude project in
10 the Athabasca Tarsands. Costs there have already
11 doubled, and some industry observers say they will
12 triple before too long. The applicant, Canadian Arctic
13 Gas, says that it wants to raise the money from the
14 worlds' large investors and lenders. . So far none of
15 it has been found. Given the present state of the
16 economy, a recession -- the worst recession since
17 1930, with no end in sight -- there must be a fair de-
18 gree of doubt hanging over the prospects of raising
19 these billions. Even the less costly Syncrude project
20 required government aid to save it.

21 It is not within the terms of
22 reference of this enquiry to look into these issues --
23 those relating to gas supply and demand and the financial
24 stability of a pipeline. None of the participants will
25 be allowed to bring in evidence on these questions.
26 Therefore no one should think that our presence before
27 this enquiry implies our acceptance of the assumptions
28 that Arctic gas will soon be needed in the south or that
29 this pipeline is inevitable.
30

Perhaps you will recall, Mr. Commissioner, the occasion when Prime Minister Trudeau compared the Mackenzie Valley Pipeline favorably to the building of the C.P.R. What the Prime Minister neglected to mention at the time he made that comparison was the fact that for the native people in Southern Canada, the C.P.R. was a disaster. It meant the loss of their land and the slaughter of the buffalo herd upon which their livelihood depended.

Perhaps you will recall, Mr.

1 It is with a view to
2 avoiding this sort of fate that the Native people of
3 the North will take the position before this Inquiry
4 that there should be no pipeline before a land claims
5 settlement. This is the position which the Metis
6 Association and the Indian Brotherhood were instructed
7 to take by a joint general assembly of their membership
8 held last summer in Fort Good Hope. That meeting
9 was the largest gathering of status and non-status
10 Indian people ever held in the Northwest Territories.

11 It was also at that assembly
12 that the Indian people of the Northwest Territories
13 reasserted their claim to ownership of over 400,000
14 square miles of land. The claim has been recognized as
15 valid by the Supreme Court of the Northwest Territories
16 in an historic judgment of Mr. Justice William Morrow.

17 The legal basis of the claim
18 rests on clear evidence that the land has been used
19 by the Native people since time beyond memory. The
20 Crown also claims the land. Negotiations between the
21 Federal Government and the Native organizations over
22 the claim are now in preparation and should get under
23 way in the near future.

24 We will urge upon this Inquiry
25 the view that the construction of a pipeline, or of
26 any other major development for that matter, prior
27 to the completion of a land claims settlement will have
28 an intolerably prejudicial effect on negotiations.
29 It is impossible to negotiate fairly over your land
30 if the steam shovels are digging up your backyard.

1 We will produce evidence to
2 show how a pipeline would interfere with the use of
3 the land by Native people. Research now underway
4 will enable us to transform the map of the Mackenzie
5 district from an apparently uninhabited wilderness
6 to a network of tracks and lines depicting extensive
7 hunting, fishing and trapping areas. The Mackenzie
8 River Valley is one of the areas where the use
9 of the land by Native people is most heavily concen-
10 trated and if I may take a moment to illustrate this
11 point, this is a map of a section of the Mackenzie
12 River Valley around Fort Norman. Here is Fort Norman,
13 this is the MacKenzie River.

14 On the map on the wall, Fort
15 Norman appears about half way down, just across from
16 the western tip of Great Bear Lake. This is a result
17 of our research, Mr. Commissioner, it represents
18 the trap lines of approximately 30% of the adult
19 males of Fort Norman. We will be producing similar
20 maps for the entire Mackenzie Valley, plus other parts
21 of the Mackenzie District. We will be filing this map
22 with the Inquiry.

23 Our thesis -- "No pipeline
24 before a land claims settlement" -- is more than just
25 a request designed to protect our bargaining position.
26 It is the formal expression of a more fundamental issue
27 which will be before this Inquiry. The issue is one
28 which involves the struggle between two opposing
29 concepts of economic development for the North.

30 The pipeline proposal repre-

1 sents the colonial philosophy of development. Opposed
2 to this notion of Northern development is the
3 "community" philosophy of development as exemplified
4 by the Native land claim.

5 What are the characteristics
6 of these two philosophis of development: the "colonial"
7 philosophy and the "community" philosophy?
8 The colonial school of economic development is the one
9 promoted by the American multi-national corporations
10 and their Canadian subsidiaries. They see the
11 North as the storehouse of resources for the industrial
12 centres of the South -- Chicago, New York, Pittsburg,
13 Montreal and Toronto. Oil, gas and minerals move
14 south to these centres. The profits which they generate
15 move south along with them. The North becomes a
16 hinterland dependent on the south; it loses its
17 resources and gets welfare in return. It is never
18 permitted to develop an economic base which allows
19 its people and particularly its native people to
20 enjoy the benefits of equality with the residents of
21 the industrial south.

22 For the Native people of the
23 North the injustices of the "colonial" philosophy of
24 development are cruelly multiplied and rubbed in.
25 In the process of building a pipeline, native sociey
26 would be dragged from a land based economy, hunting,
27 trapping and fishing -- into a wage economy, a wage
28 economy which would be the poor Northern cousin of
29 the southern economy. The big petroleum companies will
30 move in and suck dry the reserve of gas and oil from

1 the North. After they have gone what happens to the
2 Native people who must continue to live here? What
3 will be left for the owners of the land after Canadian
4 Arctic Gas and its pipeline are just a memory? The
5 "colonial" philosophy of development leaves them
6 nothing, except the desolation of a ghost town.

7 The "colonial" philosophy of
8 Northern development means prosperity for the multi-
9 national corporations. But for the North it means a
10 weak, distorted economic existence, and cultural and
11 political retardation.

12 Is there an alternative to
13 this dismal outlook? There is, and it is found in
14 the vision of hope and dignity which characterizes the
15 'community' philosophy of development and which is the
16 foundation of the land claim advanced by the Native
17 people of the Mackenzie District.

18 By claiming ownership of the
19 land, what the Native people are saying is this:

20 As much as possible we want to be able to control
21 our own destiny. We want to be the ones who
22 decide what directions our society should take.
23 We also want to participate in Canadian society
24 but we want to participate as equals. It is
25 impossible to be equal if our economic devel-
26 opment is subordinated to the profit oriented
27 priorities of the American multi-nationals.

28 Therefore, the Native people are saying, we
29 must have a large degree of control over our
30 own economic development. Without that

1 control, we will end up like our brothers and
2 sisters on the reserves in the south: continually
3 powerless, threatened and impoverished.

4 Only community ownership of the land, land
5 which has belonged to our people for thousands
6 of years, can give us the ability to determine
7 and follow our own way.

8 These then are the two
9 philosophies of development competing in the
10 arena of this Inquiry, Mr. Commissioner: the "colonial"
11 philosophy and the "community" philosophy. The
12 decision to accept one or the other will weigh
13 heavily in the outcome of the struggle.

14 The main interest of the
15 Indian Brotherhood and the Metis Association in this
16 Inquiry centres around the issue of the land claim;
17 but we will also do our best to examine critically the
18 application by Canadian Arctic Gas, or anyone else,
19 for a right-of-way in the Mackenzie River Valley. We
20 will be especially concerned with the Applicant's
21 case as it relates to the social and economic impact
22 of the proposed pipeline.

23 On the basis of material
24 already filed with the Inquiry by Canadian Arctic
25 Gas it will be necessary for us to assert that the
26 Applicant, Canadian Arctic Gas, has not adequately
27 assessed the potential impact of the pipeline and that
28 it does not really care about the long-term effects
29 of this project on the social fabric and economic life
30 of the North and its Native people. To Canadian

One other aspect of this Inquiry

1 deserves our attention before we conclude our opening
2 remarks. It concerns a question which no doubt is
3 on the minds of many people as we commence these
4 hearings today. What is a realistic estimate of the
5 time it should take to complete this Inquiry? It
6 is impossible to predict with certainty how long
7 this inquiry will last. All we can say is that there
8 is likely to be a lengthy process. There will be
9 two types of hearings: formal hearings and community
10 hearings. The formal hearings have been divided into
11 several main topics each of which will be dealt with
12 in a separate phase of the Inquiry.

1 In the interest of fairness
2 to all parties, there are certain procedures which we
3 must follow at the formal hearings. During each phase
4 we will hear the witnesses for Canadian Arctic Gas
5 first. Following their testimony each of the other
6 ten participants will be given an opportunity to cross-
7 examine these witnesses. Then each participant will
8 be permitted to call its own witnesses, with further
9 opportunity for cross-examination by the other parti-
10 cipants, including the applicant. Members of the general
11 public who wish to ask questions and offer testimony
12 will also have to be accommodated.

13 Add to this the time it will
14 take to visit the 20-odd northern communities which would
15 be directly affected by the pipeline, plus hearings in
16 southern centres for those members of the public who
17 will be unable to come to Yellowknife to express their
18 views. After the hearings, of course, the Commissioner
19 will need time to write his report.

20 It will be a lengthy process,
21 but it will be a necessary process. This pipeline
22 would bring with it other major developments, an
23 oil pipeline has already been announced, a highway is
24 under construction, a railroad is being studied. Will
25 there be a public enquiry for each of these develop-
26 ments? Maybe. Maybe not.

27 This enquiry is being asked
28 to ascertain what will be the public interest in
29 northern development for the next few decades. Surely
30 we must take all the time we need now while we have

1 the chance. Remember, this enquiry is a study whose
2 magnitude is unprecedented in the history of our
3 country.

4 In conclusion, Mr. Commission-
5 er, we wish to say again, welcome to the north. It is
6 our sincere desire to assist you in whatever way we
7 can to assure that the Mackenzie Valley Pipeline enquiry
8 is full and fair.

9 As we all get to know each
10 other better, Mr. Commissioner, I'm sure you will find,
11 as I have that the native people of the north, are proud,
12 self-reliant people, a people gentle in their manner,
13 but imbued with a sense of determination born no doubt
14 of generations of struggle with adversity. You will
15 find them to be a diverse people, a people united in
16 their resolve to command their own future and to live
17 in harmony with all Canadians.

18 All of which is respectfully
19 submitted.

20 THE CHAIRMAN: Thank you.

21 Just a moment. Mr. Scott, we
22 are going to adjourn. We'll adjourn for 15 minutes for
23 coffee and we'll reconvene at 12 o'clock sharp.

24 (PROCEEDINGS ADJOURNED FOR 15 MINUTES)

25 (PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

26 THE CHAIRMAN: Mr. Bayly?

27 MR. BAYLY: Mr. Commissioner,
28 my name is John Bayly of Yellowknife, and I act as
29 counsel for the Inuit or Eskimo people, through
30 their organizations the Committee for the Original

1 People Entitlement known as COPE and the Inuit Tapirisat
2 of Canada generally referred to as I.T.C. I.T.C. is a
3 national organization which represents Canada's Inuit
4 population across the entire north. COPE is a region-
5 al organization and represents the Eskimos of the Western
6 Arctic and in particular the people of the Mackenzie
7 Delta and the Western Arctic Islands.

8 COPE and I.T.C. are partici-
9 pating in the Mackenzie Valley Pipeline hearing because
10 the proposed pipeline, processing plants, gathering
11 systems and gas exploration work are being done and
12 built, and are proposed to be done and built on lands
13 and in waters that are traditionally, historically and
14 are presently being used and occupied by Eskimo people
15 in their traditional pursuits and way of life.

16 It is perhaps a historical
17 piece of bad timing but the pipeline hearings will
18 occur prior to the settlement of the Inuit land claims
19 and that they will commence prior to formal negotiations
20 for a land claim settlement with the Federal Government.
21 COPE and I.T.C. have not taken the position, however,
22 that they will refuse to participate in the Berger
23 hearings because of this bad timing. On the other
24 hand, the participation of COPE and I.T.C. is based
25 on the preliminary stand that there must be no major
26 development before the question of land claims has been
27 settled. The Inuit emphasize that the lands and waters
28 along the Arctic coast and in the Mackenzie Delta over
29 which Arctic Gas seeks its right-of-way are theirs.
30 The lands and waters already being used by gas and oil

1 exploration companies are theirs. No treaties have
2 been signed, no rights have been given out, and the
3 Canadian Courts have begun to recognize aboriginal
4 rights. It is commonly asked of the native groups,
5 "what do they want?"

6 I cannot go into details of
7 the land claims negotiations at this time, but it is
8 public knowledge that COPE and I.T.C. are not prepared
9 simply to bargain their aboriginal rights for a cash
10 settlement. The real issues in the negotiations
11 will deal with lands and waters and the control of
12 them. Your Commission, sir, will be looking into
13 competing land and water uses both traditional and
14 contemporary, and will no doubt in your recommendations
15 design to ensure that one use of these lands and waters
16 does not destroy the possibility of other uses.

17 COPE and I.T.C. take the
18 position that the Berger enquiry is the place where
19 they should discuss these issues as they relate to the
20 needs and desires of the Inuit in the Mackenzie region
21 and the Western Arctic Islands. We have all seen what
22 has happened in the James Bay region where the Hydro
23 Quebec Power project was partially complete before land
24 claims negotiations got under way.

25 COPE and I.T.C. do not wish
26 to see their people placed in this kind of position
27 of having to negotiate a settlement in the shadow of
28 a partially completed mammoth project. In this con-
29 text, sir, you have stated in your preliminary rulings
30 that you will allow evidence relating to land claims to

1 be led by the native groups. COPE and I.T.C. see this
2 as an important element of the Berger enquiry because
3 it will bring sharply into focus the extent of native
4 uses of the lands and waters and the conflicts that
5 will arise when these uses are compromised, changed or
6 made impossible by development.

7 In order to prepare for the
8 land claims negotiations, COPE and I.T.C. have been
9 extremely busy. In late 1972 work was begun on the
10 land claims legal brief , and this work is near com-
11 pletion. Out of that research questions have been
12 raised about hunting, fishing and trapping rights.
13 Legal research has been done in these areas as well.
14 In addition, in co-operation with the Federal Govern-
15 ment and a Hamilton, Ontario consulting firm ,COPE
16 and I.T.C. have prepared a land use and occupancy
17 study. This was begun in late 1973 and involved,
18 among other things, interviews with virtually all of the
19 Inuit hunters, fishermen and trappers in Northern Canada
20 and the development of maps showing traditional histor-
21 ic and present land and water use. This study, although
22 virtually complete, has not yet been published by the
23 Department of Indian and Northern Affairs. We anti-
24 cipate it being presented during the hearings.

25 More than 50 people were
26 involved in working in this project. Late in 1974
27 an inventory of renewable and non-renewable resources
28 was undertaken and is still in preparation. To prepare
29 for these hearings, four COPE field workers have been
30 at work since late October visiting every household in

1 the COPE region with the dual purpose of informing the
2 people of the application and collecting their reactions
3 opinions and information.

4 To give you some idea of the
5 magnitude of this task, one must realize that many of
6 the people knew nothing about the pipeline application,
7 and that often explanations had to be made of what natural
8 gas is, as a starting point. This work is not yet
9 complete, and indeed it could never be done satisfactor-
10 ily in the time permitted. It has progressed on schedule,
11 however, in all the communities but Holman Island and
12 Inuvik every household has been visited twice.

13 COPE and I.T.C. realize that
14 basically this is a hearing regarding the Mackenzie
15 Valley Pipeline. Nevertheless, and in spite of what
16 the Minister of Indian and Northern Affairs and others
17 have stated, it appears to be impossible to discuss this
18 project in a vacuum. It is central to the concerns of
19 the INuit of this region that gathering and processing
20 facilities be discussed and enquired into because
21 they will have a major and continuing impact on the
22 people of this region.

23 Furthermore, it appears that
24 this development is only the beginning of massive changes
25 proposed for this part of the world. Already the Minis-
26 ter of Energy, Mines & Resources and others are discus-
27 sing how to build oil pipelines in the Mackenzie Valley.
28 At the same time the Mackenzie Highway makes it slow
29 but steady progress towards the Delta.

30 Too often, sir, this kind of

1 development has been proposed, together with promises
2 that it will shepherd native peoples into the 20th
3 century. Too often it serves only to dislocate and
4 disorient native people and leave them unequipped for
5 the 20th century, stripped of their lands and waters
6 and ability to follow their traditional pursuits once
7 it has passed them by.

1 People are concerned that
2 the Mackenzie Valley Pipeline and the development which
3 would necessarily follow it, will have this effect on
4 their way of life. COPE and I.T.C. therefore are par-
5 ticipating in the hearings because of their concern
6 that their people will be left behind and that their
7 lands and waters will be irreparably changed. Because
8 of this, it is important to stress again that COPE and
9 I.T.C. take the position that the question of land
10 claims must be settled before construction begins on
11 the Mackenzie Valley Pipeline, or any other major
12 development in the area. If development is to come,
13 people wish to be ready for it and wish to participate
14 in it. If the environment is to be altered and used
15 in ways for which it has never been tested, the people
16 wish to be in a position to control and police the
17 environment in which that development takes place.

18 If codes of conduct or
19 environmental control are to be written, COPE and I.T.C.
20 wish to be there with pen in hand. If development will
21 mean change in the way of the life of the people, COPE
22 and I.T.C. wish to make proposals to facilitate lasting
23 involvement of their constituents.

24 COPE and I.T.C. take the
25 position that any proposals or recommendations that do
26 not take into account the reasonable wishes of the
27 people, run the risk of creating future problems that
28 may be far more costly in human economic terms than they
29 are worth. COPE and I.T.C. plan to participate in all
30 phases of the hearings, sir, but will rely heavily on

1 the Canadian Arctic Resources Committee and the
2 Northern Assessment Group during the first three
3 phases of these hearings. Thank you very much.

4 MR. VEALE: Mr. Commissioner,
5 my name is Ron Veale from Whitehorse. I am representing
6 the Council for Yukon Indians. Myself and Allan
7 Luke, general counsel for the Council of Yukon
8 Indians and will be appearing from time to time during
9 the enquiry.

10 The Council for Yukon Indians
11 represents all Indian people in the Yukon Territory
12 with ancestral rights, and the Council was specifically
13 organized to negotiate the land claims settlement with
14 the Government of Canada. During the course of these
15 negotiations the Council for Yukon Indians has insisted
16 that no major developments take place to further pre-
17 judice their aboriginal rights.

18 The proposed gas pipeline is
19 such a development and the Council is diametrically
20 opposed to it, until a settlement is reached with the
21 Government of Canada. In particular, the Community
22 of Old Crow, in the northern part of Yukon Territory
23 is most directly affected by the proposed pipeline,
24 regardless of whether the interior route or the prime
25 route is considered. Their life-style will be greatly
26 affected by a pipeline, and the Council of Yukon
27 Indians will devote its time to ensure that the views
28 of all the residents of Old Crow will be heard at a
29 community hearing later this year.

30 Mr. Commissioner, the idea of

1 a pipeline across the Northern Yukon is not new to
2 the people of Old Crow. They have considered it before,
3 but the implications to their life-style is a matter
4 of great anxiety to them and hopefully this enquiry
5 will add to their understanding and meet their aspira-
6 tions. Thank you.

7 MR. TEMPLETON: Mr. Commis-
8 sioner, in introducing the Environment Protection Board,
9 perhaps I should say at the outset, that our goal is not
10 to just make recommendations, or publish an impact
11 assessment, but to do whatever we can, if the project
12 goes ahead, to actually achieve environment protection.
13 This means going much further than saying what must be
14 done to protect the environment, or accepting promises
15 about what will be done. It means exerting whatever
16 influence we are able to exert to see that the environ-
17 mental change brought about by the project is kept to
18 what we consider an acceptable level.

19 The formation of the Environ-
20 ment Protection Board is a unique experiment in Canada.
21 Can a group of engineers and scientists actually in-
22 fluence this project, involved as it is with big indus-
23 try and big government, so that the environment
24 protection is achieved? We do not mean to imply that
25 many people in the industry and government are not as
26 concerned about the environment as we are, but perhaps
27 because of the magnitude of the numbers involved, the
28 inertia of these organizations might prevent a rea-
29 sonable degree of environment protection from being
30 achieved.

1 Now, who are we? The members
2 of the Board are: Dr. Larry Bliss, Professor of
3 Botany at the University of Alberta and director of the
4 Devon Island project, part of Canada's contribution to
5 the International Biological program;

6 Dr. Max Britton, a renowned Arctic
7 ecologist. Unfortunately Dr. Britton resigned from the
8 Board in September so that he could take a full-time
9 job with the U.S. Government. He is available to attend
10 part of these hearings if he is required;

11 Mr. Donald Craik, a consulting me-
12 chanical engineer and a member of the Legislature of
13 the Province of Manitoba, who as a former Cabinet
14 Minister tackled many northern problems in Manitoba;

15 Mr. Eric Gourdeau of Quebec City, a
16 forestry engineer and economist by training, and a
17 friend of the natives by association, and former
18 director of the Arctic Institute's "Man in the North"
19 program;

20 Dr. Ian McTaggart-Cowan, Dean of
21 Graduate Studies of the University of British Columbia,
22 and well known northern ecologist;

23 Dr. Stanley Thomson, professor of
24 civil engineering at the University of Alberta and
25 former engineer on the Alaska Highway;

26 Dr. Norman Wilimovsky, professor
27 of the Faculty of Graduate Studies and the Institute
28 of Animal Resource Ecology of the University of British
29 Columbia. He served as a member of the U.S. Atomic
30 Energy Commission's Committee on Project Chariot and

1 carried out a number of other Arctic studies.

2 My name is Carson Templeton.
3 I am a consulting engineer and chairman of the Board.
4 My work in the north goes back to 1942 when I was a
5 construction worker on the Canol Oil Pipeline from
6 Norman Wells to Whitehorse and helped design and build
7 the Alaska Highway -- and incidentally I did my share
8 of the terrain degradation, the signs of which are
9 still visible.

10 Now what about our goals?

11 There were six:

- 12 1. To promote openness. We believe that all per-
13 tinent environmental information, whether in the
14 hands of government, the applicants or university
15 people, should be made public and discussed pub-
16 licly;
 - 17 2. To promote discussion of environmental matters.
18 There is an informed public ready and able to
19 discuss the environmental issues and all that is
20 necessary is to present the issues and delineate
21 the important from the less important.
 - 22 3. To develop a methodology for converting
23 environmental research into environment protection
24 measures and controls.
 - 25 4. To publish an environmental impact assessment
26 of the proposed project.
 - 27 5. To monitor the effects of the project activities
28 on the environment if the project goes ahead.
 - 29 6. To publish a post-construction evaluation.
- 30

1 We have in part achieved the
2 first three goals by publishing 27 newsletters, 8
3 brochures, 3 interim reports, and a workshop proceedings.
4 We achieved the fourth with the publication last
5 September of our Environmental Impact Assessment of the
6 project.

7 We have not achieved goals 5
8 and 6 because they lie in the future. Yet goal 5 --
9 monitoring the effects of project activities on the
10 environment -- is critical. Monitoring by people who
11 do not have a line function in the project is essential
12 to check that the environmental protection measures are
13 actually being implemented. Whether we do this or others
14 is incidental.

15 Goal 6 is to publish a
16 post-construction evaluation that evaluates the methods
17 of predicting impact and the effectiveness of the en-
18 vironmental controls. This will follow if goal 5 is
19 successfully achieved.

20 The Board's annual budget is
21 funded by the sponsor, which at first was Alberta Gas
22 Trunkline Limited, later Gas Arctic, and still later
23 Canadian Arctic Gas Study Ltd. Being an autonomous
24 body and not a firm of consultants hired to do a job for
25 a client, the Board studied what it felt it should
26 study within its budget limitations. The sponsor did
27 not have the right to edit or guide our studies or our
28 opinions and our reports. For example, we gave our
29 reports to the printer before we gave a draft to the
30 sponsor. The sponsor and the Board each has the right

1 to terminate the arrangement at any time. The path
2 has been a rocky one, often difficult for each party,
3 but we have survived 4 1/2 years.

4 The Board's terms of reference
5 required that it study only the natural environment.
6 Social considerations were to be left to others.
7 However, the farther we got into our study the more
8 we recognized that the native culture was inextricably
9 intertwined with the natural environment, and that we
10 just could not forget about the people. As a result,
11 the native use of the environment was included and
12 perhaps we've gone a little farther in some aspects.
13 But we have considered only some of the social impacts
14 and none of the regional economic impacts.

15 We have asked for and been
16 granted status as a participant at these hearings.
17 We do not have a lawyer to represent us. On the one
18 hand this may make it difficult for the Commission
19 counsel and the other participants' lawyers, having
20 several laymen in their midst who are ignorant of and
21 lacking sympathy with Court room terminology and
22 procedures. On the other hand, I do not think that
23 the impact assessment process should be come wholly a
24 Court room exercise. I am sure, Mr. Commissioner, you
25 have indicated in your preliminary rulings that this
26 is not a trial.

1 But I feel that perhaps
2 some of us may, in our arguing, tend to make it such.
3 If this should happen, we all should remember an
4 important point about the environment and man's law
5 and it is this: man's law can and should respect the
6 environment, but the environment cannot and will not
7 respect man's law.

8 If at times the hearings appear
9 to become a trial, then it is man's ability to plan
10 for the future that is on trial and not the environment.
11 In a way, the future of the environmental impact
12 assessment process is at stake here. How well can
13 the economists and scientists and engineers translate
14 their studies into readily understandable impacts,
15 specifications and controls which will lead to limiting
16 environmental change to a predetermined level.

17 How well can they separate
18 the important effects of the project from the non-
19 important effects and reach some kind of quantification
20 or comparison of costs and benefits? This is not
21 an easy job. I am sure that all of us are unhappy
22 that we cannot be more precise. We would like to be
23 able to assign a number to each impact, like dollars,
24 to the debit and credit side of the ledger, but this
25 cannot be done. All one can do is study the natural
26 environment, study the proposed project description,
27 estimate the alterations which will be caused by
28 it and spell out the controls needed to see that the
29 alterations are kept to the predicted levels.

30 This is a subjective process

1 that advances by study, experience and above all,
2 honesty. There is nothing wrong with a subjective
3 process and the fact that the environmental impact
4 assessment process is subjective does not lessen its
5 validity.

6 Perhaps I seem a little overly
7 defensive about this, but too many people seem to expect
8 a magic unit to appear to be used to measure environmen-
9 tal costs and benefits, so that an environmental
10 statement similar to a financial statement can be
11 drawn up. There can be no such magic unit. The
12 application of mature judgment is the only available
13 means of measurement.

14 I have only one other point
15 and that has to do with the control of the project.
16 I regard the matter of effective control as a major
17 issue because without it there will be no environmental
18 protection. Responsibility for controlling the pro-
19 ject lies with two distinct groups: the Applicant
20 and the Government. I have assumed that control of
21 the project will be discussed here. Even though the
22 four phases of the hearings which are headed Engineering
23 and Construction, Impact on the Physical Environment,
24 Impact on the Living Environment, and Impact on the
25 Human Environment, do not specifically refer to it.

26 What I hope is that the
27 hearings will specifically address the role of
28 Government in controlling the project. This might
29 very easily be overlooked but the role of Government
30 is probably the most significant factor in

1 determining whether the project, if it goes ahead, is
2 an environmental success or failure. I would like
3 to illustrate how easily this point might be overlooked.
4 In Volume II of our report, headed "Towards an Environ-
5 mental Code", we listed the duties of the Government
6 agency as well as those of the Applicant. This month
7 we received the first draft of the "environmental
8 guidelines for gas pipeline development" put out by
9 the Ecological Protection Branch, the Environmental
10 Protection Service, the Department of the Environment.
11 In many places the guidelines agree very closely with
12 what we said in our code, but there is absolutely no
13 mention of the agency that would control the project,
14 its duties or its responsibilities.

15 I bring this up only to point
16 out that it would be very easy for people to say, "Oh,
17 we have environmental guidelines to control the
18 project", and at this point they usually tap you on
19 the head and say, "It is being looked after." But
20 as you can see by the top of my head I have been tapped
21 quite a few times already. My efforts of getting
22 the Federal Government to publish an environmental
23 impact statement of the Mackenzie Valley Highway has
24 been very hard on my head.

25 But the guidelines will not
26 control the project in themselves. We may find as
27 so many other projects in the past that enough was
28 known about protecting the environment but it was
29 just not done. I therefore hope that these hearings
30 will detail the Government's role in protecting the

1 environment in the same detail as it does the applicant's.

2 On this matter of guidelines
3 without control I am reminded of an analogous situa-
4 tion that occurred in a paper mill, which I had some
5 dealings, which is a very noisy place to work.
6 The industry issued sound retarding earmuffs to the
7 employees and made it a rule that the earmuffs were
8 to be worn in the mill, but because the workers could
9 not see an immediate need for the earmuffs, they
10 flaunted the rule and subsequently impaired their
11 hearing. Not until the industry policed the wearing
12 of earmuffs, did the millworkers actually protect
13 their hearing.

14 In the same way these
15 hearings are expected to protect the social fabric
16 and the environment of the North from degradation.
17 Not just in the words that are spoken but in the
18 final fact when the project is finished if it
19 goes ahead. During these hearings all of the parti-
20 cipants and perhaps two levels of Government will be
21 making some promises and implying some commitments to
22 the people of Canada. If we do not see that these
23 commitments and promises are actually accomplished
24 we will have failed.

25 When the Board held meetings
26 with the Native peoples at Aklavik last year, an
27 Inuit Victor Alan spoke eloquently about Northern
28 pollution. His definition of pollution was different
29 than ours. He referred to it as the pollution of
30 broken promises. I hope that when these hearings are

1 finished we will not have set the scene for what
2 by Victor's definition will be the pollution of the
3 North.

4 Thank you.

5 MR. SIGLER: Mr. Commissioner,
6 my name is Murray Sigler, from Yellowknife. I am
7 a member of the Alberta and Northwest Territories
8 bar and in this Inquiry I will be appearing as Counsel
9 for the Northwest Territories Association of Municipi-
10 palities. In my remarks to day I will try to be as
11 brief as a lawyer can be and just try to give an indi-
12 cation of the background of membership of the Associ-
13 ation itself, why the Association is come to be in-
14 volved in these proceedings and what that involvement
15 and position may likely be.

16 I will start off by saying that
17 the Northwest Territories Association of Municipalities
18 was formed in 1967 and since that time it has grown
19 and continued to act more strongly as a central
20 co-ordinating agency for the various municipal councils
21 in the Northwest Territories. Today, and in speaking
22 throughout this Inquiry, the Association of Municipal-
23 ities is speaking for the elected municipal governments
24 of the City of Yellowknife, the Town of Fort Smith,
25 the Town of Hay River, the Town of Inuvik, the Town
26 of Pine Point, the Village of Fort Simpson, the
27 Village of Forbisher Bay, the Hamlet of Pangnirtung,
28 the Hamlet of Ray, Edzo, and the Hamlet of
29 Tuktoyuktuk.

30 The municipal councils

1 which are members of the Association represent approxi-
2 mately 70% of the population of the Northwest
3 Territories and about 80% of the population of the
4 Mackenzie district. As elsewhere in Canada all
5 the municipal councils in the Northwest Territories
6 are fully elected by the people in the communities.
7 The association, and I should stress that it is not
8 only representative of the majority of the people in
9 the communities to be affected by any pipeline, but
10 that representation in membership cuts across interest
11 group and racial lines. The position of the municipal-
12 ities in these proceedings is not for or against the
13 Applicant or for or against any other participant.
14 We are speaking only for the municipal councils elected
15 by the people in the settlements, towns, etc., in-
16 volved.

17 The municipalities are inter-
18 ested in these hearings not only from an academic
19 point of view, not only because a pipeline development
20 may have a great social economic impact on all the
21 people in the Mackenzie District Municipalities.
22 Apart from all that I think that the municipalities have
23 a perhaps more important interest in these hearings
24 and a very special one, for no matter what is said
25 or promised or arranged or decided or negotiated or
26 recommended or whatever, the municipal councils will
27 be the ones, as a level of government who will be
28 responsible for picking up the pieces and dealing with
29 the social and economic aftermath on a community level
30 throughout the Mackenzie District and for that matter,

throughout the Northwest Territories wherever development on a major scale, even on a smaller scale, will or is likely to occur in the future.

Perhaps it is fair to say that no other group before this Inquiry will be more concerned with the ongoing social, economic impact than will be the municipalities as represented by the Northwest Territories Association. Why the concern? Well, first of all the legislative responsibility of municipalities as set out in the Municipal Ordinance for the Northwest Territories, embraces several areas of relevance in considering the potential impact of a pipeline. These areas include: general municipal government administration, providing protection services for the communities, providing transportation services, the licensing and regulating of businesses. (Any business carrying on its operations in a municipality must be licensed), the services of providing sanitation and waste removal, providing public health providing recreation services which cannot be overlooked in the human impact and in the rapid growth of any communities that might be affected by any development, providing the utilities, of course, which is directly a concern, as far as the pipeline development goes, and very importantly, I will mention last, that the function of developing land for housing and for any other purpose within the municipal boundaries.

1 That's what municipalities are
2 for, and not only involved in these hearings because of
3 the social effects of the pipeline development, on the
4 people, they are also involved because it is their
5 responsibility and their burden as municipal government
6 to do something about the effects in providing services
7 to the residents of all these communities.

8 Since the job of the Municipal
9 Council is and will continue to be, to ensure the well-
10 being of municipal residents, it will be crucial that
11 the municipalities be given the means to prepare for
12 changing events and the means to solve the accompanying
13 problems. We would ask this enquiry to give serious
14 attention both to these problems and possible solutions
15 in its final recommendations.

16 In light of the requirements
17 and concerns of the municipalities, their involvement
18 in these hearings will take the following format:

- 19 1. Each individual Municipal Council plans to and
20 will be expressing directly their special local
21 concerns at the community hearings. As with the
22 Indian Brotherhood of the Northwest Territories
23 and Metis Association positions that have been
24 enunciated to you earlier, we feel that the
25 community hearings are most important phase of this
26 enquiry. We feel this is where the enquiry will be
27 able to get the grassroot feelings of the people
28 of the north, and we'll be hearing from the people
29 themselves. We agree that this job probably will
30 be much better done by the people themselves than

will be through any counsel.

As with some of the other participants, we have been active in Professor Jackson's Committee in trying to come up with the best format, and scheduling of the community hearings. We cannot stress the importance of these community hearings to us.

2. Our second level of involvement will be with Mr. Reesor, the executive director of the Association, who will be present throughout the entire course of the formal hearings themselves, with assistance from myself as counsel when required.
3. During the fourth phase of the hearings, the Association will be represented throughout by counsel and during the fourth phase the Association will be introducing formal evidence, including the study which is now being prepared by consultants to the Association, and which will set out the common concerns and priorities felt by the municipalities regarding the proposed development. This submission will -- we feel our submission is badly required, we feel the applicant -- the application itself is lacking in its social-economic side of its material, and our submission will attempt to provide helpful information to the enquiry and from the areas we feel are important but have been missed by the applicant.

Our submission will first of all provide to the enquiry, an indication of the magnitude and nature of the impact the pipeline generated growth may be expected to have to each of these subject

municipalities.

Secondly, our submission will provide discussion and analysis of the implications of such impact.

Thirdly, we hope to provide recommendations relating to those actions which might be considered in order to minimize the negative aspects and maximize the positive aspects of anticipated municipal growth.

Fourthly, our submission will hope to provide a forum for the expression of community concerns as enunciated by the Council of each subject community.

Fifthly, we hope to give some indication of a regional-owned gas potential in various areas. Perhaps of most direct interest to the applicant, our submission will review, thoroughly analyze and recommend strategies in supplying gas to the local communities in the Mackenzie region.

Lastly, our submission will comment upon the timing of any construction of any proposal to enable the municipalities to prepare for themselves fully and properly to ensure that the people within the municipalities obtain the proper municipal services.

We do not want to be placed in a similar position as municipalities such as Fort McMurray in Alberta with the Syncrude project.

In conclusion, it is, I think, fair to suggest that all local northern groups represented

1 at this enquiry are rapidly developing a common frus-
2 tration that many important decisions directly affecting
3 the future of all northerners are being made or will be
4 made elsewhere than in the north, and by people other than
5 northerners, yet it will be us, the northerners, who
6 will be left behind after all is said and done to
7 salvage our lands, our communities, and our personal
8 life-styles.

9 It is for this reason that all
10 northerners are elated that these hearings are now
11 being held in the north, and that all local individuals
12 councils and organizations will have the opportunity
13 to make known their legitimate concerns.

14 It's fair to say that this,
15 to the people of the north at least, these hearings
16 are being eyed as more than technical recommendations
17 regarding pipeline right-of-way. They've become a
18 symbol for all their common hopes, fears and aspirations
19 regarding our growth in the future. Notwithstanding
20 both the national and international concerns and con-
21 siderations to your hearings, we are confident that
22 this time the local people will not be overlooked or
23 forced to take a back-seat position in the determina-
24 tion of their own future growth and development. It
25 is in such a context that the Northwest Territories
26 Association of Municipalities fits in, and I think
27 helps explain both the basis of the concern of municipal
28 government and their role at these hearings.

29 That's all I'd like to say on
30 behalf of the Association, I'd like also to mention that

1 the Northwest Territories Chamber of Commerce will be
2 represented at the fourth day of the hearings only
3 by my partner, Mr. Searle of Yellowknife, who is unable
4 to make the hearing today.

5 MR. SCOTT: Mr. Commissioner,
6 that concludes the statements that are to be made by
7 the continuing participants in the enquiry. I should
8 have brought to the attention of the persons here,
9 including the participants, that a transcript on a
10 daily basis of what is said, not only today but on each
11 day succeeding in which evidence is taken, is being
12 prepared and it will be available to be read or inspec-
13 ted or reviewed by any member of the public at the
14 following places:

15 First of all at the Commission Offices in Yellowknife,
16 which are in the Resources Building;

17 At the Commission Offices in the City of Ottawa;

18 At the Public Library in Inuvik;

19 The Public Library in Whitehorse; and

20 The Public Libraries in Edmonton and Calgary.

21 In the event that on the way
22 to complete his N.E.B. filings at Ottawa, Mr. Gibbs
23 wishes to inspect one in Toronto, one will be available
24 there as well.

25 Mr. Commissioner, tomorrow
26 we commence with the overview evidence that will be
27 called, subject to your preliminary rulings, by Commission
28 counsel. We propose to begin, if you please, sir, at
29 nine o'clock in the morning sharp. I should tell
30 participants that -- and members of the public -- that

1 the following week we will commence phase 1, the
2 commencement dates and hearing places for the other
3 phases of the enquiry will be announced in due course
4 as we get toward them.

5 That's all I have to say, Mr.
6 Commissioner.

7 THE CHAIRMAN: Well, we will
8 adjourn then until nine o'clock tomorrow. We will
9 resume at nine o'clock sharp tomorrow morning.

March 4, 1975.

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

THE COMMISSIONER: Mr. Scott?

MR. SCOTT: Mr. Commissioner, before we commence with the overview evidence, I would advise that Mr. Anthony has something that he wishes to raise with the Commission, and I think it appropriate that he might be called on first.

MR. ANTHONY: Mr. Commissioner, I have a matter I think of some urgency. It requires that I rise and speak to you at this early date. I have advised Commission counsel yesterday evening and this morning, and I am appreciative of the consideration given in allowing this matter to be raised at this time.

In the opening statement that the Canadian Arctic Resources Committee made yesterday we outlined some of the problems that we as an intervenor and as an environmentalist had experienced in obtaining some of this necessary environmental information, the difficulty in getting government documents, the inaccessibility of the Department of Environment witnesses.

Now in our attempt to make a realistic assessment of the environmental situation for in particular, phase 2, which while we have no set time-table, may arrive as early as six or eight weeks, a considerably short time, given the fact that we will be involved in the day to day activities of this Commission up to that time.

Now, Mr. Commissioner, you have advised us that this will be a full and a fair Inquiry and C.A.R.C. now finds itself in the position of being the only environmental representative on a continuing basis throughout the Inquiry, and we would find great reassurance and restore our hope and confidence that all the relevant environmental issues will be raised if this Commission was able to inform us the method and in fact the fact that the Department of Environmental witnesses who have relevant testimony to this Inquiry will be available.

1. We would respectfully ask that you would instruct Commission counsel to forthwith -- I was going to say write, but the mail perhaps -- telex the Minister of the Department of Environment and then convey to the participants before you, before this Inquiry, the advice of the Minister that the Departmental experts who have relevant evidence to offer this Inquiry will be made available to this

1 Inquiry at government expense to present their
2 evidence.

3 2. Alternatively, that this Commission could give
4 assurance that on request of participants,
5 Commission counsel will arrange for the presence
6 of witnesses at the expense of Commission counsel
7 if Commission counsel is satisfied that they have
8 relevant evidence that should be before this
9 Inquiry.

10 We are somewhat reluctant to
11 put so much emphasis on the question and the problems of
12 ensuring attendance of government witnesses; but it is
13 clearly recognized that the reasonable costs of travel
14 are significant, and that the cost of ensuring that these
15 government witnesses attend are considerable. Should
16 the participants be forced to rely on powers of subpoena
17 then the normal rule would require the participants
18 like ourselves and native organizations and other
19 major participants to pay these witnesses their
20 expenses. This we simply cannot do. Nor I think is
21 it fair or even logical that an intervener such as the
22 Canadian Arctic Resources Committee or any other native
23 groups should be required and should bear the burden
24 of calling a Department of Environment witness because
25 the Department of Environment has chosen not to present
26 its evidence itself. I think the people of Canada
27 would be disappointed and shocked to think that the
28 agency of the Government of Canada responsible for
29 protecting the environment was not going to be present
30 and the responsibility of getting this evidence was to

1 fall to parties such as the Canadian Arctic Resources
2 Committee, or indeed any other participant before this
3 Inquiry.

4 I would suggest, Mr. Commission-
5 er, that unless we have some assurance that either of the
6 alternative forms can be followed, then our efforts in
7 this Inquiry will be frustrated. We feel strongly
8 enough in this matter, and the matters we referred to
9 -- other matters referred to in our opening statement
10 about the provision of documents that we've already
11 asked for from the Government of Canada, that we must
12 tell you realistically what our problem and what our
13 position is.

14 We suggest that it would be
15 impossible for us to be ready to launch into phase 2,
16 the environmental impact phase of this hearing by
17 the end of April, which is a likely date for such
18 evidence to come forward, unless we have these documents
19 at the very earliest date, and unless we have some
20 indication of the availability of the witnesses within
21 I would say two or three weeks. At that time if it
22 appears that we cannot adequately deal with the environ-
23 mental issues we've identified as being significant,
24 because these documents and other evidence have not
25 been provided, it may be necessary for us to request
26 this Commission for adjournment until this information
27 can be available to the Inquiry, alternatively, we would
28 have to limit our participation to those environmental
29 issues that concern us which we can properly lead
30 evidence independent of the work of the Department of

1 the Environment or information from the other parts of
2 the Government of Canada.

3 We are anxious that this
4 Inquiry move forward as quickly as possible, and we are
5 committed, as I know this Commission is, to ensure that
6 that takes place. But the present situation is complete-
7 ly unproductive, especially the government, and frustrat-
8 ing to those who are trying to move this matter ahead
9 and ensure that the relative evidence is here.

1 We respectfully, Mr. Commis-
2 sioner, therefore ask that you give these directions
3 to Commission Counsel to insure that we have the
4 complete evidence before us and that the evidence of
5 the Government of Canada is forthcoming and the
6 personnel are available to this Commission.

7 I am sorry to take the length
8 of time in making that point, but we feel that this
9 is a vital issue and we respectfully submit this
10 for your consideration

11 MR. BELL: Mr. Commissioner,
12 I think that in view of the interest that the public
13 has and that the people that I represent have in
14 seeing that the environmental case, the entire environ-
15 mental case is before this Commission that the Indian
16 Brotherhood of the Northwest Territories and the Metis
17 Association of the Northwest Territories would support
18 the Canadian Arctic Resources Committee in this
19 request.

20 MR. VEALE: Mr. Commissioner,
21 the Council for Yukon Indians also supports C.A.R.C.
22 in this and we are relying a great deal on the evidence
23 that they will be able to present to this Inquiry.

24 MR. BAYLY:
25 And the same is true, Mr. Commissioner for C.O.P.E.
26 and the Inuit Tapirisat.

27 MR. GIBBS: I have no repre-
28 sentation to make.

29 MR. GENEST: I have no represent-
30 ations to make.

THE COMMISSIONER: Mr. Scott.

1 MR. SCOTT: I would like
2 to thank Mr. Anthony for bringing to my mind
3 early today his intention to make this request of
4 the Commission. I would like, if you will permit,
5 to be able to defer my response to it until shortly
6 after lunch. I do not think any harm will be done
7 by giving us that opportunity to consider it in some
8 detail.

9 MR. ANTHONY: Mr. Commissioner,
10 I have been asked to say in public that that is fine
11 with us and we would appreciate hearing from Commission
12 Council at his convenience this afternoon.

13 MR. SCOTT: Well, Mr. Commis-
14 sioner, we now commence the overview evidence. I
15 set out yesterday, in a general way, reading from
16 your rulings, but it was intended to include and the
17 way that it would be conducted. It should be clearly
18 understood that the evidence that will be brought
19 before you in the overview is designed to provide a
20 technical backdrop against which the position of the
21 applicant and the intervenors, which will be led
22 commencing next week, may be seen and examined.

23 The preliminary rulings
24 determine two important matters with respect to the
25 overview. First, that there will be no cross-examina-
26 tion of overview witnesses at this stage so that the
27 matter may proceed promptly, and secondly, the determina-
28 tion that if any participant or interested party wishes
29 to recall a witness who gives evidence at the overview,
30 for cross-examination at a later or other stage of the

J.G. Fyles
In Chief

1 Inquiry, that we will arrange to effect that recall
2 so any questions can be put to him. That, in short
3 is the framework of the overview evidence and I am
4 ready to begin by calling our first witness.

5 Dr. Fyles.

6 JOHN GLADSTONE FYLES, sworn.

7 THE SECRETARY: Would you
8 state your full name, please.

9 A John Gladstone Fyles.

10 DIRECT EXAMINATION BY MR. SCOTT:

11 Q Dr. Fyles, you are such
12 a familiar figure to those of us in this Inquiry
13 that I hesitate to ask you to tell us anything
14 about yourself, but I think for the purposes of the
15 record you might tell us something about your
16 educational qualifications and your expertise.

17 MR. GENEST: Mr. Scott, we
18 cannot hear you over here.

19 MR. SCOTT: I am sorry, Mr.
20 Genest. You will read that question tomorrow
21 morning.

22 A Mr. Scott inquired about
23 my educational qualifications. I have undergraduate
24 degrees in geology from the University of British
25 Columbia, a Masters Degree in the same field from
26 the University of British Columbia and a PhD. from
27 Ohio State University with specialization in those
28 aspects of geology that deal with the terrain,
29 landforms, the surface of the earth, the unconsolidated
30 soil materials and the processes that are at work on

1 the surface of the earth and this respect I contrast
2 with those geologists whose main concern is with
3 rocks and the minerals although gas is not my field.

4 Q Well now since your
5 graduation with those degrees, Dr. Fyles, will you
6 tell the Commission to what extent you have been
7 engaged in your field and where.

8 A I practiced in this
9 field for approximately 25 years as an officer of
10 the Geological Survey of Canada. Nine field seasons
11 have been spent in the Northwest Territories and in
12 the Yukon.

13 Q Do I understand that
14 during that nine year period you were engaged doing
15 field investigations in your territory?

16 A Yes.

17 Q Now I also understand
18 that from 1971 to 1973 you were the co-ordinator
19 of Research, that the Department of Energy, Mines and
20 Resources contributed to the Environmental Social
21 program Northern Pipelines in the Mackenzie Valley.
22
23
24
25
26
27
28
29
30

J.G. Fyles
In Chief

1 A Yes.

2 Q And that latterly, in
3 1974 you served as the leader or director of the
4 Government of Canada Pipeline Application Assessment
5 Group.

6 A That is also correct.

7 Q Now, Dr. Fyles, I would
8 just ask you to carry on. There will be interruptions
9 perhaps from me or the Commissioner if there are points
10 of clarification that are required, and I trust you'll
11 understand that.

12 A I'm quite prepared to be
13 interrupted.

14 Mr. Commissioner, the swearing
15 in ceremony with the Bible in my hand has reminded me
16 that there is a parable in the Bible about -- in which a
17 wise man is identified as one who has sense enough to
18 build his house upon a rock, and when the winds blow and
19 the rain comes, the house does not fall down. I suppose
20 we might comment paranthetically that the builder of
21 this hotel certainly was a wise man.

22 Then the parable goes on to
23 refer --

24 THE COMMISSIONER: To the
25 elevators.

26 A The elevators are not
27 a foundation problem. The parable goes on to comment
28 that a foolish man would build his house upon the
29 sand or upon the earth, and would run the risk of
30 having some kind of a disaster, from the movable forces

1 of nature. I think what I want to say to you today
2 relates to the rock and the soil and these forces which
3 act upon the structures which man has built upon them.

4 Now, contrary to this Biblical
5 injunction, most development activities of man come to
6 rest upon the sand, upon the soil, rather than upon the
7 rock. This is a rather deliberate thing, you know it's
8 much easier to build things on the unconsolidated soil.
9 You can dig into it. You can pile it up in heaps. It's
10 generally flat rather than rock. You can use it for
11 fill to make roads and so on. You can pour wastes and
12 water into it and they become absorbed. Besides that,
13 90% of the surface of Canada is soil rather than rock.

14 This is all fine, and the
15 Biblical story is all fine, in the temperate regions.
16 In the north, however, another parameter comes upon the
17 scene. Rock is still rock; but soil, now filled with
18 ice and cemented together, becomes in a way a kind of
19 rock, and some of it's comparable properties that
20 builders and engineers are so used to dealing with in
21 south, have disappeared, it becomes expensive to
22 excavate. The excavated material may contain enough
23 ice which, when melted, the material loses its strength.
24 The excavations left behind may slump and may become
25 a kind of seepy, messy area. It's difficult to dispose of
26 wastes or to obtain water.

27 So we have a special situation
28 in the north, which has a very real bearing upon the
29 works of man in the north. This morning I am to provide
30 a very general review of the physical attributes of the

J.G. Fyles
In Chief

1 region. I will deal with things which are common, a
2 number of them common knowledge, everyday things, and
3 perhaps I can provide a very general backdrop for the
4 more specific things that will be said later in the
5 day by Professor MacKay and Professor Church who will
6 deal with more specific, more detailed topics.

7 I will make my remarks to a
8 series of slides which will be shown on these two
9 screens. I trust that we won't run into writing
10 problems.

11 THE COMMISSIONER: Excuse me,
12 Dr. Fyles, I'm having a little difficulty hearing you.
13 Are all you gentlemen able to hear?

14 MR. GENEST: I have difficulty
15 too. /I think it may be that you could speak a little
16 louder. I think another problem is there's too much
17 noise in here and maybe if we could all pay attention
18 to Dr. Fyles, Mr. Genest and I might have a fighting
19 chance of hearing what he's saying.

20 Carry on.

21 A Right. I thought perhaps
22 at the outset it was worth saying, "where are we in
23 Canada in the course of these hearings, and where are
24 we today?"

25 The concerns that we'll be
26 dealing with relate to that northern half of the
27 proposed pipeline route within Canada, roughly half of
28 the length. Now this is a rather substantial distance,
29 and you'll note that from here to here is roughly the
30 same as if one were to go from Vancouver over to Regina,

J.G. Fyles
In Chief

1 or from Toronto back to Winnipeg. So that it's quite
2 a large region and we certainly can't expect it to be
3 all the same. In the north-south direction in passing
4 from, for instance, Inuvik to Yellowknife, one has to
5 traverse in a north-south direction approximately the
6 same distance as if one were to go from Yellowknife
7 southward to Edmonton. The total north-south distance
8 in the area that we're concerned with is almost equal
9 to the north-south length/here, ^{of the province} and perhaps it's worth
10 noting that this is the middle part of Canada and that
11 there is an equal section of Canada even farther north.

12 Of course, despite the fact
13 that it is the middle part of Canada, in a sense, it is
14 a northern region, a cold region, the Arctic circle
15 passing through here, so that the northern part of the
16 region has periods of continuous darkness and continuous
17 -- in the winter, and continuous sunshine or light in
18 the summer. Very cold winters and an Arctic -- at least
19 a Northern climate.

1 But fortunately the climate
2 in Canada is not an east - west phenomena and for
3 those of you who can see this particular slide, these
4 are the temperature maps for Canada for the summer
5 months of June, July and August with the average
6 minimum temperature on this side and a maximum
7 temperature on this side, and the darker colours
8 representing warmer temperatures and the lighter
9 colours cooler temperatures, with the yellow
10 just about at freezing and I direct your attention
11 to this phenomenon showing up here in the minimum
12 temperature for June, or in the maximum temperature
13 for August, or the minimum temperature for August,
14 namely that in the area that we are concerned with,
15 the temperatures are equivalent to those substantially
16 farther south if one were to go east in Canada.
17 If one were to go directly eastward from this area
18 would pass into a colder region.

19 So we have a warming distri-
20 bution of the temperatures in the summer, into the
21 region that we are concerned with, so it is not
22 quite so arctic as one might think.

23 Now, this trend is illustrated
24 by the permafrost map of Canada, a subject which
25 Professor McKay will deal with in some detail later
26 and you will note that the area we are concerned about
27 and the Great Bear Lake here,
28 Great Slave lake here, and the coast here, lies within
29 the permafrost region, but the boundaries between
30 the various kinds of permafrost, the more severe in
the north and less severe in the south, trend, quite a

1 northerly trend, so that we have conditions in our
2 study region, much of our study region equivalent to
3 those substantially south in Manitoba, Ontario,
4 Quebec and the kind of intense situation you might
5 find at this same latitude farther east is only
6 found in the coastal zone.

7 Now, vegetation is another
8 indicator of climate and in this map shown on the far
9 screen you see the vegetation regions of Canada and
10 again the same trend with the forest extending well
11 down the Mackenzie Valley and the northern limit of
12 trees only along the coast, whereas farther east of
13 course you have the barren lands coming much farther
14 south.

15 So, in the southern part of
16 the region they have quite large forests and it is
17 only as we get very close to the coast that you
18 get this treeline situation and even at the outer
19 -- outermost land along the coast, there is still a
20 fairly substantial cover of green growing things.
21 The Rock Desert with scattered plant assemblages is
22 not a characteristic of the lowland area along the
23 Mackenzie Valley, but rather is a function of the
24 Arctic Islands and the mountain regions to the
25 west of the Mackenzie Valley.

26 Within our region, of course,
27 climate is not uniform and I am not going to try and
28 go into any detail, but this map illustrates a very
29 distinct zonation of climate, but along the Mackenzie
30 Valley a progressive change from south to north to a

1 whole series of zones and then more severe situation
2 and
3 to the east/in the mountains to the west and the
4 zone along the coast somewhat modified by the presence
5 of the sea.

6 Another -- there are many
7 aspects of climate that I could talk about and I do
8 not propose to go on to a lot of them. One though
9 that I will mention briefly is the matter of precipi-
10 tation. This map shows the number of days in the
11 year that there is precipitation in Canada and you will
12 note that the region that we are concerned with, like
13 the prairies, lies within one of the regions with the
14 smaller amount of precipitation. The darker colours
15 are those of high precipitation, and the lightest
16 colour are those with -- large numbers of days with
17 precipitation and the light colours are those with
18 small number of days with precipitation.

19 Now, of course, this does not
20 mean to say that the region is dry. Much of the ground
21 surface in the summer is very wet indeed. This is
22 partly a function of the low temperatures and partly
23 a function of the presence of an impermeable perma-
24 frost barrier a very short distance below the surface
25 which prevents water from draining into the ground.

26 Now, let us look at the physic-
27 al attributes of the region. This map of Canada shows
28 the Mackenzie Valley in green and Great Slave Lake
29 through to the coast and on a larger scale you can
30 see it better. The dark green colour is -- represents
areas within 500 feet of sea level. The paler green

1 is area within a thousand feet of sea level, so we
2 have a large low region with high mountains to the
3 east and a plateau region -- to the west, a
4 plateau region to the east and a substantial lowland
5 along the coast.

6 The pale blue area lies less
7 than 500 feet below sea level so that we have a
8 lowland along the coast which is much broader than
9 that which shows above the sea.

10 Through this region, of course,
11 flows the Mackenzie River and this map shows the
12 river discharge and provides us with an idea of how large
13 the Mackenzie is compared with the other rivers of
14 Canada and how it ranks with the St. Lawrence in its
15 magnitude. It is truly one of the great rivers of the
16 world with many and contrasting moods.

J.G. Fyles
In Chief

1 Canada may be divided into
2 a number of distinct landscape units or areas of con-
3 trasting character, so we have the snow, the Canadian
4 Shield shown here in pink, the corridor, the mountains
5 shown in blue, the interior plains shown in yellow,
6 and what's less familiar to most people, Arctic coastal
7 plain extending along the west side of the Artic Islands and
8 into Alaska, and as I said a few moments ago, it's got
9 a very bad submerged portion.

10 Now of course, we don't have
11 to go very far outside the door to see what the Canadian
12 Shield is like. It's the same whether one is in
13 Ottawa, or Loon Lake, or North Bay, or a lot of other
14 places, or in the barren regions up near Coppermine.
15 An area of hard rocks, little knobby hills, all kinds;
16 of course the mountains come in all sizes and shapes
17 with rocks inclined in different directions. The
18 interior plains, the yellow area, if one were to
19 strip the vegetation you could imagine yourself some-
20 where near Saskatoon or Edmonton or, as in this case,
21 Arctic Red, an area of low relief and flat line, soft
22 rocks. Or perhaps one might imagine oneself in
23 the Niagara Gorge instead of in the ramparts of the
24 Mackenzie. There are great similarities in the interior
25 plains region, whether you're here or right around here.

26 The coastal lowland region
27 up in here is quite different, although in a way it is
28 an extension of the interior plains. You can see it
29 perhaps better in that blown-up section of the map,
30 lying astride the mouth of the Mackenzie River. Here,

J.G. Fyles
In Chief

1 for instance, we have a view at Shingle Point west of
2 the mouth of the Mackenzie River with the coast plain
3 about 10 miles wide and the Richardson Mountains
4 beyond. Or looking along Richards Island, one of the
5 minor channels in the Mackenzie Delta, the Delta on
6 this side and the rolling hills of the lowlands on
7 the other.

8 Now for the most part the
9 Mackenzie River lies within the interior plains, but
10 in this area in the vicinity of Rigley to Norman Wells,
11 the river ducks in behind an outer range of mountains.
12 Here at Norman Wells, looking north, you see this outer
13 range of mountains, the river, and what is called the
14 Mackenzie Plain, which lies along the river and between
15 the outer range of mountains and the main Mackenzie
16 Mountains.

17 Looking again at these mount-
18 ains from above the river, you can see the relatively
19 steep sided escarpments, a series of ridges.
20 The Mackenzie Plain along the river where Port Norman
21 and Norman Wells are situated is partly underlain by a
22 soft rocks, sands, and shales, and partly by the lime-
23 stones which form the mountains which are dissolved in
24 sink-holes such as this.

25 The area I've been talking
26 about, of course, is in here where the mountains go
27 out beyond the Mackenzie River and where the river and
28 the pipeline route are confined. Now this map is like the
29 last one, showing the physiographic regions but it is
30 really a part of the Mineral Map of Canada. Just to

J.G. Fyles
In Chief

1 refresh our memory of such matters, of course numbers
2 of mines of mineral deposits in this shield area whether
3 one is in Northwest Territories or Ontario or Quebec, like-
4 wise numerous mines & mineralized areas within the mountains
5 of the Cordilla.

6 The interior plain has a few
7 mines and mineral deposits, such as the one at Pine
8 Point and hopefully there will be other Pine Points in
9 the future, but of much greater interest at this moment
10 is the matter of oil and gas reserves. Here is the north-
11 ern end of the Athabasca Tar Sands and some of these
12 blue and red spots marked "Oil and Gas Fields" in
13 Alberta. The black circles which we plotted on the
14 map here represent the presently known discoveries of
15 oil and gas in the Northwest Territories. You see that
16 to a very large degree they lie within the interior
17 plains, in the coastal plains to the north, and on the
18 fringe of the -- in part on the outer edge of the
19 mountains here and in the Eagle Plains there. So we
20 have a shot of the delta showing the seismic activity,
21 one of the oil well rigs, and the coming back down
22 to Norman Wells, there is a refinery at Norman Wells
23 which is an oil field within this part of the mountains
24 and not in the interior plains.

25 Now I'll change my subject at
26 this point and start talking, instead, about the larger
27 features of the earth and deep in the earth, some
28 of the surface features. This photograph, of course, is
29 not of the Mackenzie Valley, it's one of the ice-caps
30 in the Arctic Islands, and I'd like to remind you that

J.G. Fyles
In Chief

1 all of Canada with the exception of this part of the
2 Yukon, was some 15,000 years ago, down to 10,000 years
3 ago covered by a great ice sheet that extended from
4 the Atlantic Coast to the Arctic Coast over in here.
5 This ice sheet had some substantial effect upon the
6 land surface. Of course, there are striking land
7 forms resulting from the movement of the ice across the
8 ground, but more particularly important to us, the
9 ice movement created materials which form the surface
10 of the earth. This is a stony glacial till which is
11 the rubble picked up and left behind by the glacier
12 as it moved across all of Canada. I've chosen rather
13 a stony example because many photographs we have of
14 glacial till look like a dirty grey concrete, so that
15 they're not all as bouldy as this and I trust that
16 construction in the Mackenzie Valley will not encounter
17 too many things of this nature. They are known to be
18 present. Glaciers also have rivers associated with
19 them which leave deposits of gravel in all sorts of
20 opportune and inopportune places, and are used exten-
21 sively in construction throughout the country and in
22 -- and will be used in the Mackenzie Valley as well as
23 elsewhere.

24 Now one of the things associa-
25 ted with the ice sheet was a complete change in the
26 drainage. Of course the ice covered land so the
27 river systems came to an end and stopped. Then as the
28 ice retreated, lakes formed in various places, partly
29 the result of damming of drainage and partly as a result
30 of depression of the land surface by the weight of the

J.G. Fyles
In Chief

1 ice. In this map the green colors show areas of Canada
2 which, at one time or another, were under lakes after or
3 during retreat of the ice sheet.

4 Now these lakes were some
5 of them very large, some of them very small, and the
6 thing I'd like to bring out at this moment is the
7 clays which were deposited on the land surface at the
8 bottom of these lakes. Now this sample of these layers
9 about an inch thick, looks very innocent and quite
10 solid. These clays may be quite considerable thickness,
11 several tens of feet in thickness, and they're very
12 wide-spread in Canada. But solid though the material
13 may look, they are the source of many engineering
14 foundation problems, whether one is at Winnipeg, Regina
15 or here at Fort Simpson where part of the river bank
16 has slumped away through the instability of these clays.

17 This map shows the distri-
18 bution of glacial lake clays in the southern part of the
19 Mackenzie Valley. Here is Fort Simpson, and the west
20 end of Great Slave Lake is approximately here, so there
21 is a substantial area of clay shown in blue through
22 into here and up in the vicinity of Rigley. Along here,
23 Norman Wells and south of Fort Good Hope, and even in
24 the region of Artic Red.

25
26
27
28
29
30

1 Now, of course, after --
2 sorry, I have to reverse this -- when the ice sheet
3 covered the whole region of course there was no
4 vegetation at all, except in those areas that were not
5 ice covered. There were no plants and no animals so
6 that as the ice retreated the animals, the vegetation
7 and the fish and so on migrated back in and some
8 elements of the distribution of these even today
9 reflect the pattern of remigration into the country.

10 With the disappearance of
11 the ice, all the normal processes that act on the
12 land surface by wind and water and slope movement
13 took over. So of course the rivers like the Mackenzie
14 here at Fort Rigley, cut down below the level of the
15 plain left behind by the glacier and small streams
16 eroded gulleys of all shapes and sizes.

17 Because of the coldness of
18 the climate, the ground in substantial areas became
19 permanently frozen, with ice in it and ice ridges in
20 certain areas worked their way down from the ground
21 surface. These form interesting patterns over the
22 landscape throughout the area that we are concerned
23 with and each of these cracks will have an ice wedge
24 beneath it or has had an ice wedge beneath it in the
25 past which has now melted out as a result in changes
26 in climate.

27 Here is an abandoned air-
28 strip and you can see the pattern of the ice wedge
29 is retained even though the area has been cleared
30 and used by man.

1 On flat ground all sorts of
2 hummocks, knobs and miscellaneous things of this type
3 have developed through frost movement in the active
4 layer that seasonally develops above the permafrost
5 surface.

6 On slopes, gentle slopes such
7 as this, the process is one of general down slope
8 creep and differential movements lead to a striping
9 of the ground with joining linear bands of slightly
10 different character and supporting slightly different
11 vegetation and with a different drainage characteris-
12 tics.

13 This photograph at the top
14 is here and the ground slopes away and down this way.
15 Of course, on steeper slopes things have a tendency
16 to fall down hill so one gets rubble of various
17 kinds. This thing is a rock glacier which I will not
18 try and explain today, it will take too much time, but
19 it is a distinctive slope form of rock rubble and then
20 of course there are many kinds of earth failures on
21 slopes and river banks.

22 Now, one thing that is of
23 considerable importance in the surface of the land of
24 the region, of course is the development of vegetation,
25 the development of soils and the build up throughout
26 a great, a large part of this region of a layer
27 of organic matter or peat. In some places only a few
28 inches in thickness, but in other places in the order
29 of more than ten feet. Now, this of course changes
30 the character of the surface material. It of

1 course absorbs a lot of water, it is sort of like
2 an intermatted mesh of things that hang together
3 and retard erosion and of course is an insulating
4 blanket which changes the whole temperature regime
5 of the ground. The development of this organic mat-
6 erial in layers of different thickness creates a
7 distinctive landscape. This is entirely a peat land-
8 scape with the ridges such as this, frozen peat and of
9 course the ponds in between and the fen areas un-
10 frozen.

11 If one looks at this
12 from the ground or standing in one of the unfrozen
13 fen areas and looking to a frozen ridge of peat,
14 roughly ten feet higher than a person standing on top
15 and if one were to dig a trench through that ridge
16 that a person was standing on, from one of the fen
17 depressions on one side or the other, it would look
18 something like this with a whole series of layers
19 of peat down on to the mineral soil. In the middle
20 of the summer, or early in the summer, the ground
21 surface would be thawed something like so -- with a
22 remnant of the winter ice or frost in the ground
23 underneath the fen, but no further frozen material, but
24 beneath the mound of frozen peat of course the
25 continuous frozen ground, down to some unspecified
26 depths below.

27 Now, I have tried to show
28 you in these slides that the land surface is a dynamic
29 one with various active processes taking place which
30 man in his works can take advantage of or run counter

J.G. Fyles
In Chief

1 to or accelerate or decelerate, depending on his
2 successes and failures.

3 Now, we have been talking
4 about the area that was covered by the glacier, the
5 ice sheet, chiefly along the Mackenzie Valley and I
6 would like to just briefly say something about this
7 light area, the unglaciated area, where the normal
8 processes of rivers and wind and slope movement,
9 freezing and thawing have gone on for many millenia.

10 Here on the eastern flank --
11 sorry --

12 THE COMMISSIONER: Excuse
13 me Dr. Fyles. The leg of the proposed pipeline from
14 Prudhoe Bay to Travaillant lake will pass over the un-
15 glaciated area, would it?

16 A Yes, that is correct.
17 The eastern -- the western edge of the glaciated area
18 lies along the eastern edge of the mountains and down
19 to about into here, like so, so that the interior
20 route crosses into the unglaciated area. The slide
21 on my -- on this side, is roughly along the mountain
22 front here and you can see the glacial materials of
23 the lowlands, they cover overburden and drift and the
24 unglaciated mountains beyond where the surface materi-
25 als all are simply rock rubble.

26 Now, if one passes across
27 this -- the Richardson Mountains into these inter-
28 mountain basins, we come upon quite a different land-
29 scape. Here there are broad sloping benches which
30 are called pediments which have developed as a result

1 of water erosion and down slope creep on the bedrock
2 surface. Here is another view of the same sort of
3 thing and characteristically high up near the mountains,
4 these are covered by quite coarse rubble derived from
5 the bedrock, only a few feet in thickness, and as one
6 comes lower and lower down into the basin the over
7 burden material is progressively thicker and finer
8 textured and of course will contain more ground
9 ice and then through these benches the rivers are
10 cut, valleys of various sizes and depths and down
11 in the floors of the basins such as here at Old Crow,
12 the Old Crow Flats, they are thick, fine-grained ice
13 ridge sediments, thick cover of peat on the top and
14 of course many lakes.

15 Now, -- so that is the
16 unglaciated area in a very brief nutshell.

17 Now, let's look equally
18 briefly at the Yukon portion of the Coastal Plain
19 and then at the other part of the Coastal Plain.
20 so if we go across the mountains to the coast and
21 look back, this low plain, not very much relief, on
22 the coast, muddy slopes or sandy slopes cut into
23 by the sea, much ice in the material, bedrock not
24 exposed generally on the coast and of course in the
25 summer time you still have this sea of ice hanging
26 fairly close in.

27 Many of the rivers, particu-
28 larly in the western part and even more particularly
29 in the western Canadian part here, more particularly
30 in Alaska, flow on broad, flat flood plains in a braided

1 pattern with the channels changing continuously in
2 position and size as the season changes. This white
3 thing down here is the mid-summer remnant of an
4 icing which developed during the winter, through water
5 continuing to move through the gravels of the river
6 bed and coming to the surface certain places and
7 continuing to flow and freeze on the surface buildup.
8 A large body of ice which will last through a good
9 part of the summer. These are quite a common feature
10 of these braided river beds.

11 Of course, not all of the
12 rivers are braided like that, and here is a segment
13 of the Fort Pine caribou herd migrating through this
14 area.

15 Now, if we go over to the
16 opposite side of the mouth of the Mackenzie, we have
17 the other part of the coastal plain and here we are
18 on the Tuk peninsula approximately up there.
19 Now, this is an aerial view of Tuktoyaktuk here
20 with the Dew Line facing over there and it gives
21 the impression of a country almost awash, low hills,
22 and a coast which is eroding in certain places and
23 building out bars and spits in other places. This
24 photograph was taken looking eastward, at midnight,
25 so you can see the long shadows of the pingos pointing
26 almost due south.

27
28
29
30

The coast, as I said, is rapidly eroding in some places, such as this muddy cliff and building beach bars in other places. The coast is an accident of sea level. I would draw your attention again to this map and this zone which lies only less than 500 feet below sea level. Somewhere on one of these things -- that's the one -- I recall the matter of glaciation. Here we are in the coast -- the Northwest Territories-Yukon coast -- and at the maximum

J.G. Fyles
In Chief

1 of glaciation, there is a great body of ice extending
2 off in this direction, across the continent of North
3 America and on other northern lands. These ice
4 sheets extracted a lot of water from the sea with the
5 result that the sea level is lower, so at the time
6 when the area was covered by the ice sheet, the ocean
7 level was lower and a substantial part of the coastal
8 plain was exposed above the sea. Then as the ice
9 melted, of course, the sea rose again across the coastal
10 plain and we now have former land which now lies
11 off-shore from the Arctic coast.

12 Now I would now like to --
13 before I move this I would like to draw your attention
14 to this lobe here, which marks the mouth of the Mackenzie
15 River, and there was a rather major lobe of the glacier
16 which extended down a deep valley, which is now occupied
17 by the mouth of the Mackenzie. So in this slide we
18 have the Yukon coastal plain here which is the Herschel Island
19 and the Alaska border approximately here, and Richards
20 Island and Tuk Peninsula over on this side, and
21 between this valley which can be traced outward to the
22 continental slope, a valley some 30-40 miles wide, and
23 those of you who are close enough can see figures on
24 this thing, indicating the thickness of the Mackenzie
25 Delta sediments across, the sea bottom is flat, almost
26 flat, and from sounding methods, we have demonstrated great
27 thickness of sediments across here which has been used
28 to demonstrate the seaward continuation of this valley,
29 and of course this part of it has still not been filled
30 in by the river. So this is the Mackenzie Delta, the

J.G. Fyles
In Chief

1 outer part with the eroded slopes of the old valley
2 on both sides. I think the next slide shows this view
3 of this -- no, sorry, this is earth's photograph showing
4 the Mackenzie Delta, with the Tuk Peninsula and
5 other parts of the coastal plain here, the Yukon
6 coastal plain there, and the front of the Richardson
7 Mountains here, and the muddy waters of the Mackenzie
8 showing up as pale blue, and these channels going out
9 there and dumping mud out into the bay and
10 mud coming out this way and sweeping off into this
11 direction.

12 Now as I was saying a moment
13 ago, the next slide shows the eastern edge of the
14 delta depression, here an ice-snow road on the east
15 channel with the abandoned settlement of Ranger Depot.
16 and the front of the Cariboo Hills a few hundred feet
17 in height. Here we are in the outer part of the delta
18 looking sort of southward and westward to the Richardson
19 Mountains off to the west. You can see the steep front
20 of the mountains which mark the western edge of the delta, and
21 of course the typical pattern of river channels and
22 lakes which are so commonly portrayed as a typical
23 photograph of the Mackenzie Delta, the delta behaving
24 sort of like a sponge or sieve and as water levels rise
25 during flood season, water goes into the small channels
26 and thus takes mud into the lakes and then during lower
27 water periods the flow is reversed.

28 The higher or inland portions
29 of the delta are forested and the river banks which
30 vary in height, depending on the season of the year,

J.G. Fyles
In Chief

1 are under-cut by the river; whereas in the outermost
2 part of the delta new sediment and new land is added
3 each year as the spring floods bring down more and more
4 silty mud. This is Shallow Bay out in here.

5 With that, Mr. Commissioner,
6 I think perhaps I should not take the subject any
7 farther.

8 THE COMMISSIONER: Thank you
9 very much, Dr. Fyles.

10 (WITNESS ASIDE)
11 MR. SCOTT: Mr. Commissioner,
12 the carol of slides has to be changed, so could I
13 suggest a 10 or 15-minute adjournment while that is
14 done?

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

MR. SCOTT: Mr. Commissioner,
our next overview witness is Dr. J. Ross McKay, a
Professor of the Department of geography in the Univer-
sity of British Columbia. Dr. McKay?

JOHN ROSS MCKAY, sworn:

THE SECRETARY: Will you
state your full name, please?

THE WITNESS: John Ross McKay.

DIRECT EXAMINATION BY MR. SCOTT: Dr. McKay, I
understand you are a Professor of the Department of
Geography in the University of British Columbia, is
that correct?

A That is correct.

Q And that you are a Ph.D.
in the University of Montreal.

A That is correct.

Q What was the subject
or the discipline of your Ph.D?

A In Geography, in the
study of geomorphology.

Q Yes. I understand that
commencing in 1946 until 1949 you were on the staff in
that subject at McGill University.

A That is correct.

Q And since then, since
1949 and currently you are at the University of British
Columbia in that discipline.

A That is correct, yes.

J.R. McKay
In Chief

1 Q And that at the University
2 of British Columbia you are presently teaching two
3 courses on the subject of permafrost.

4 A That is correct.

5 Q One course would be enough
6 for us.

7 (LAUGHTER)

8 A It might well be.

9 Q Dr. McKay, I understand
10 that for 20 full seasons you have been in the Western
11 Arctic three months each, engaged in field work, is
12 that correct?

13 A That is correct.

14 Q What is the nature of the
15 field work that you've been doing in brief?

16 A Primarily a study of
17 the origin of permafrost and the ground ice in it,
18 along the Mackenzie Valley and the Western Arctic coast.

19 Q Yes, and I take it that
20 in that period of time you have taken a series of
21 field trips down the Mackenzie River to the coast.

22 A Yes, we worked about six
23 times down the full length of the Mackenzie River.

24 Q Yes. I also understand,
25 doctor, that you have served on numerous national and
26 international committees on matters connected with
27 permafrost.

28 A That is correct, yes.

29 Q And that in addition to
30 that work your publications and your main research

J.R. McKay
In Chief

1 interest for many years have been associated with
2 permafrost with specific reference to the origin of
3 ground ice.

4 A That is correct.

5 Q Now, doctor, would you
6 carry on, if you please?

7 A Thank you. Mr.
8 Commissioner, ladies and gentlemen, in today's overview
9 hearing on the physical environment of the Northern
10 Yukon, the Mackenzie Valley, Dr. Fyles has placed the
11 region in its appropriate physiographic, geologic and
12 climatic setting. I have been asked to give an over-
13 view of permafrost, omitting the hydrologic, geotechnical
14 and ecologic aspect which will be discussed by others
15 in subsequent sessions.

16 Permafrost is a clearly
17 defined technical word. It is often used rather
18 incorrectly as being synonymous with ice. Permafrost
19 refers to a temperature condition of the ground.

20 THE COMMISSIONER: Excuse me,
21 Dr. McKay. Are you gentlemen able to hear this?

22 MR. GENEST:
23 I am having difficulty, doctor. Perhaps it's my own

24 THE COMMISSIONER:
25 ears. Well, this is a public hearing. Excuse me,

26 Dr. McKay, I'm sorry to interrupt you. Are you
27 people, members of the public, able to hear what is
28 being said?

29 THE PUBLIC (IN CHORUS): Yes.

30 THE COMMISSIONER: Well, it
may be your own ears.

(LAUGHTER)

J.R. McKay
In Chief

1 THE COMMISSIONER: Well, we'll
2 carry on and I really would appreciate it if we could
3 all give our attention to Dr. McKay and then I think
4 we'll all be able to hear you. Carry on, sir.

5 A Thank you. Permafrost
6 refers to a temperature condition of the ground in
7 which the temperature below zero degrees Celsius or
8 32 degrees Fahrenheit has existed for a long time, a
9 period which may extend from 2 to tens of thousands of
10 years. The word "permafrost", then, is defined
11 solely upon two criteria: namely a temperature below
12 zero degrees Celsius and a minimum age measured in years.
13 It is most important to stress the fact that the presen-
14 ce or absence of ice is not relevant to the definition
15 of permafrost. This distinction is essential t o our
16 discussion. For instance, a permafrost site at Yellow-
17 knife can be an ice-free bedrock. That is up in there.
18 An off-shore permafrost site along the Yukon coast may
19 be in sea bottom sediments where the pore water being
20 saline has no ice at minus 5 Celsius. Other sites can
21 have ice, but no excess water is produced when perma-
22 frost is thawed. By "excess water" is merely meant the
23 following: If we take a glass and we fill that glass
24 with soil and if we thaw the soil in the glass, if
25 the soil is moist there is no excess water; but if
26 there is free water or stagnant water above the soil
27 then there is excess water.

28 So examples where very little
29 excess water are the pore ice of sands and gravels
30 clays with a high unfrozen pore water content. That is

J.R. McKay
In Chief

1 clays can be frozen at below zero Celsius and still
2 have the pore water unfrozen. Other sites can have
3 abundant excess ice so that a large surplus of water is
4 released when permafrost thaws. Examples are the ice
5 ridges along the Yukon coast.

6 Segregated ice which underlies
7 nearly half of the Townsite of Inuvik, pingo and obtru-
8 sive ice near Tuktoyaktuk, and ice ridge organic peaks
9 in many parts of the Mackenzie Valley. Yet permafrost
10 includes all of the preceding examples. It is obvious,
11 therefore, that if permafrost and ice-free bedrock at
12 Yellowknife is warmed to above zero degrees, nothing
13 happens to the properties of the rock, because there
14 is no phase change from ice to water.

15 What if a permafrost site at
16 Yellowknife contains excess ice? Thaw would lead to
17 surplus water, possible instability and subsidence.
18 Consequently our concern today is not with permafrost
19 in general but specifically with the role of ground
20 ice in permafrost. I should like to stress most
21 emphatically that although I will be concentrating on
22 ground ice, there are very extensive areas of the
23 Northern Yukon and Mackenzie Valley where ground ice
24 is very sparse. But these areas are omitted from the
25 present discussion.

26 Origin and distribution of
27 permafrost. Permafrost can only occur at sites where
28 the mean annual ground temperature is below zero Cel-
29 sius. This slide shows approximate mean annual ground
30 temperature, the lowest about minus 9 Celsius or 15

J.R. McKay
In Chief

1 degrees Fahrenheit are along the coast, whereas some
2 temperatures above zero are encountered at Fort Simpson,
3 Fort Providence, and Yellowknife. For example, along
4 the coast the mean annual ground temperatures are above
5 minus 8 or minus 9. As we come down, minus 4, minus 4,
6 minus 2, minus 3, minus 1, and we come down to the
7 Fort Simpson-Yellowknife area, some of the temperatures
8 are positive and some of them are negative. Ground
9 temperatures are, of course, a direct response to air
10 temperatures. In general, mean annual air temperatures
11 are from 3 to 5 degrees colder than the corresponding
12 ground temperatures. The winter snow cover helps to
13 insulate the ground and keep it warmer than the air.
14 That is in the Mackenzie Valley and the Western Arctic
15 coast, the air temperatures are about four degrees
16 colder than the ground temperature, and as air temper-
17 atures change, ground temperatures change and perm_afrost
18 is the response to air temperatures.

19 This slide shows the generalized
20 temperature changes with depth at a permafrost site.
21 The vertical latches indicate depth of the ground.
22 The horizontal latches is temperature with positive
23 or above freezing temperatures on the right, and nega-
24 tive or below freezing temperatures on the left. The
25 two curves are for the maximum and minimum temperatures
26 reached at any given site.
27
28
29
30

A permafrost map can be very misleading if it is literally interpreted and if an allowance is not made for the great variability of permafrost in a small area, such as a square mile. For example, Dr. R.J. E. Brown of the National Research Council has measured some ground temperatures at Yellowknife and this is depth in meters, five, ten, so

1 that is 15 feet -- 30 feet. This is temperature
2 along the bottom, so this is zero in there, - 1, + 1.
3 We see that the range in ground temperature at Yellow-
4 knife is more than two degrees Celsius with sites
5 of spruce and sedge having permafrost, these two
6 sites here are in permafrost whereas the other
7 three sites in a burned area, in an area of granite,
8 and glacial till which Dr. Fyles mentioned,
9 have no permafrost. This indicates the variability
10 of permafrost at any given site.

11 Passing on then to ground ice.
12 A very generalized classification of ground ice is
13 shown in the slide. On the left hand column is the
14 water source, in the centre column the transfer
15 process which brings water to the freezing site and
16 on the right examples such as an ice wedge, pore
17 ice, cavity ice, pingo ice and segregated ice.
18 When surface water trickles into vertical cracks and
19 freezes, ice wedges form. That is if we take surface
20 water, moved it by gravity into vertical cracks, we
21 have ice wedges. When subsurface water freezes in
22 place, pore ice forms. If you take sub-surface
23 water, we freeze it in place, we have pore ice.
24 When sub-surface water moves by vapor diffusion
25 we have cavity ice. When subsurface water moves
26 under a pressure potential we have pingo ice and
27 under a thermal potential we have segregated ice. We
28 today are most concerned with ice wedges and segrega-
29 ted ice because of their high ice content. Pore
30 ice and pingo ice are of lesser interest than cavity

1 ice which will not be discussed which is only,
2 unfortunately, I suppose of academic interest.

3 The ice types to be considered
4 in sequence then are ice wedges at the top, pore
5 ice, pingo ice and segregated ice.

6 THE COMMISSIONER: Mr.
7 Scott, that is a slide that I think in due course
8 should be marked and appear in the transcript.
9 I only make that comment now so that you and the,
10 reporter will understand that. Carry on Sir, please.

11 (SLIDE MARKED EXHIBIT 49)

12
13 A The ice wedge on the
14 left is ten feet wide at the top and 25 feet deep.
15 The ice wedge is composed of nearly pure ice.
16 Another ice wedge seen in the ^{oblique} section is on
17 the right. there is one on the left and there is the
18 one on the right. The ice wedge exposures along
19 a coastal bluff at Garry Island one hundred miles
20 northwest of Inuvik.

21 In flat areas ice wedges
22 produce a polygmal pattern where troughs delimit
23 the ice wedges. Under each one of these troughs
24 there is an ice wedge similar to the one in the
25 preceding slide. It might be smaller, it might
26 possibly be larger. The polygon shown here are
27 roughly about perhaps one-quarter the area of this
28 room. Polygmal patterns are a good sign of under-
29 lying ice wedges, however, on hill slopes steeper
30 than about four degrees, down slope soil movement

J.R. McKay
In Chief

1 tends to mask trough development and so the presence
2 of ice wedges may not be visually evident even though
3 they are abundant. We can see ice wedges here, but
4 on the hill slope back there they are also present,
5 but not easily, visually detected.

6 Ice wedges are formed by
7 thermal contraction of the ground in winter and by
8 infilling by melt waters in May and June. During
9 the late winter, usually in February, cracks
10 may open in the ground and penetrate downwards as
11 much as 15 feet. So, here then are ice wedge cracks
12 exposed obviously by the removal of snow.

13 The cracks begin to close
14 in the spring, but if snow melt enters the crack
15 before it is completely closed, a thin vertical ice
16 vein becomes sealed in permafrost. What happens
17 then is that the snow melts, water runs down that
18 crack, since that crack penetrates into permafrost,
19 that portion of the ice vein that freezes there is
20 preserved in permafrost.

21 Repeated cracking and infilling
22 along this zone of weakness may produce over some
23 thousands of years ice wedges many feet in width, so
24 here we have an ice wedge forming in the first winter,
25 water runs down there and freezes, the first fall we
26 have ice preserved in permafrost, the active layer
27 thaws, this process cycles on then for some thousands
28 of years, and in a thousand and one we have an ice
29 wedge crack and thousand and two there is the ice
30 wedge. This is the mechanism of ice wedge growth.

J.R. McKay
In Chief

1 THE COMMISSIONER: Would
2 that slide be marked too in due course.

3 (SLIDE MARKED EXHIBIT 50)
4

5 A Actively growing ice
6 wedges are numerous along the Yukon Coast, the outer
7 Mackenzie Delta and Richards Island. In this
8 area in there. Ice wedges are also fairly numerous
9 south to Arctic Red River, but at the present time
10 probably most are not growing. There are ice wedges
11 here but most are probably inactive. Ice wedges
12 become fewer and fewer southwards and not many have
13 been seen south of Fort Norman although a few do
14 occur.

15 THE COMMISSIONER: That
16 slide as well.

17 (SLIDE MARKED EXHIBIT 51)
18

19 A Ice wedges are quite
20 stable features under normal conditions. For instance,
21 ice wedges can continue to grow even if fields of
22 water occupy the troughs every summer as is shown in
23 the slide. However, ice wedges are very susceptible
24 to thermal erosion if there is a sustained flow and
25 the crux is a sustained flow of water through the
26 troughs above the ice wedges.

27 To illustrate, about every
28 two years a large lake on either Richards Island or
29 Tuk Peninsula becomes drained naturally by the thermal
30 erosion of ice wedges at its outlet. This

1 slide shows one such lake that drained on Richard's
2 Island in 1964 and here is the drained lake, Dr.
3 Fyles showed a picture of a drained lake. From there
4 to there there is about a half a mile, and the lake
5 was drained by overflow through there and the over
6 flow channeled through ice wedges and drained the
7 lake.

8 In every single example that
9 we have examined in the field drainage has occurred
10 because stream flow was diverted by natural means
11 through an ice wedge system.

12 This slide shows the results
13 of ice wedge erosion for a lake which drained last
14 June in 1974. There is a man for scale, and there
15 is the drainage channel. The large gully has not
16 resulted from soil erosion, but from thermal erosion
17 of ice wedge ice.

J.R. McKay
In Chief

1 The sustained flow was de-
2 rived from snow melt and lake-over flow last May
3 and June. The gulley will probably become stabilized
4 in the next several years.

5 THE COMMISSIONER: Excuse me,
6 Dr. McKay, how long did it take for that gulley to
7 become established?

8 A I think that would have
9 eroded through in maybe two weeks. Pore ice is the
10 ice which bonds or cements soil particles such as
11 sand grains together. This is a slide that shows lens
12 ice here and pore ice. For scale, this would be
13 about two inches across, so this is pore ice and
14 that is segregated ice. Here we see the soil layers
15 bonded by pore ice with ice lenses in between. If
16 the pore ice just fills the intestices and yields no
17 excess water when thawed, then sites of pore ice are
18 usually not problem areas. Pore ice is characteristic
19 of sandy areas wherever they tend to occur.

20 Although pingo ice is not
21 of direct importance, an understanding of the mechan-
22 ism of pingo growth is relevant to our discussion, and
23 here is a pinto 120 feet high, and it has 120 feet of
24 ice below it, and there is the ice of a pingo about
25 25 feet high. This slide shows the distribution
26 of the 1,500 pingos north of Inuvik. None are known
27 to occur to the south. Nearly ever pingo has grown in
28 the bottom of a great lake. As a rough estimate,
29 pingos grow in only about one-quarter of the Great
30 Lakes, therefore probably 5,000 or more lakes have

J.R. McKay
In Chief

1 drained naturally in the past 10,000 years, that is
2 since glaciation for the 1,500 pingos to grow. A
3 substantial proportion of the lakes have been drained
4 by iceridge erosion.

5 THE COMMISSIONER: Mark that
6 as an exhibit.

7 (SLIDE MARKED EXHIBIT # 52)

8 A In any permafrost area
9 all large deep lakes and rivers have an unfrozen pool
10 of water at the bottom. If we take a large lake and
11 it is more than six feet deep it will maintain an
12 unfrozen pool of water at the bottom. This pool of
13 water being unfrozen all year, has a sufficient heat
14 reservoir to keep the ground immediately below the
15 lake unfrozen. This is zone in there. If the
16 lake or river is more than a mile wide, and it has
17 been in existence for a long time -- by that I mean
18 in the many thousands of years -- there will be no
19 permafrost beneath it, even along the Arctic coast.

20 The slide shows schematically
21 conditions for a coastal lake where the mean annual
22 ground temperature is minus 8 Celsius, and the mean
23 annual lake temperature is plus 2 Celsius, or 18
24 degrees Fahrenheit and plus 6 Fahrenheit. You see at
25 the lake, which is 500 meters or 1,500 feet in diameter,
26 from there to there is 1,500 feet, will have a thick
27 unfrozen zone beneath it. Should the lake then be
28 drained, the unprotected lake bottom will be exposed
29 to cold air temperatures equivalent to the surrounding
30 land and permafrost will commence to grow on the exposed

J.R. McKay
In Chief

1 lake bottom. If it drains and we take a temperature
2 of plus 2 and substitute a temperature of minus 8, that
3 means that we initiate permafrost growth.

4 THE COMMISSIONER: Mark that
5 slide an exhibit.

6 (SLIDE MARKED EXHIBIT #53)

7 A Pingos grow then because
8 a lake becomes drained and a lake bottom freezes over.
9 However, permafrost surrounding the lake must be
10 thick. The lake bottom sediments must be of sands and
11 not clays and drainage must be rapid; if the same size
12 lake were to be drained in the same material but at
13 Yellowknife, probably no pingo would be formed.

14 The growth of pingo serves
15 to illustrate the important point that freezing con-
16 ditions vary greatly from one permafrost area to
17 another, even in similar soil types, and in order to
18 understand the occurrence of ground ice we must try to
19 reconstruct the past permafrost conditions under which
20 the ground ice grew.

21 When permafrost grows downwards
22 a combination of a certain freezing rate, soil character-
23 istics and ground water conditions may result in the
24 formation of ice lens both small and large. Such ice
25 is referred to as segregated or lens ice. The ice lens
26 shown here is exceptionally large and pure. The ice
27 lens which is in blue is just about natural scale.
28 Usually ice lenses are interpolated with soil, there
29 can be every possible gradation between the soil with
30 a few hairline ice lenses to massive ice with only a

J.R. McKay
In Chief

1 few hairline soil laminae. Segregated ice grows when
2 the freezing plain remains stationary and when water
3 moves upwards through the soil drawn by capillarity like
4 alcohol to the flame of a lamp wick. What happens is
5 if we take away the ice lens, this material was
6 there. The freezing plain has remained stationary there,
7 water has moved upwards to the freezing plain, and formed
8 at the freezing plain and formed the ice lens above
9 the freezing plain. The ground is then uplifted by
10 an amount approximately equal to the sum of all of the
11 ice lenses which have grown. The ground will heave
12 then that amount. Conversely, if the ground is
13 eventually thawed, water equivalent to the sum of the
14 ice lenses is released and subsidence results.

15 Under natural conditions,
16 areas of thick segregated ice can usually be recognized
17 by slumping along steep bluffs which border the sea, lakes,
18 or rivers. Here, for example, is a large exposure of ground
19 ice four miles south-west of Tuktoyaktuk. An ice wedge
20 can be seen at the top. There is an ice wedge. Here
21 is the segregated ice, and the section is slightly
22 higher than this room, about 30 feet in height. Icy
23 sections such as this can fall back very rapidly.

24 Where ground ice is exposed
25 along an eroding bluff, the slump is constantly reactivated
26 by erosion. At an inland site where this erosion
27 does not occur, slumps have a lifetime of about five
28 to about 20 years; but where a slump is activated by
29 erosion, as long the coast, it goes back. This one
30 has been going back since 1935.

J.R. McKay
In Chief

1 Insofar as is known, most of
2 the massive ice lies at depths greater than 20 feet,
3 and the distribution decreases from south to north.
4 This is a collation of known data from about 15,000
5 shot-holes for the Yukon coast and adjacent areas.
6 for those holes which have encountered massive ice.
7 We see the ice as in the previous slide peaks at a depth
8 of about 40 to 50 feet. Then as we go south from the
9 coast, down towards Norman Wells, insofar as we know the
10 abundance of ice decreases from north to south. In
11 general, massive ice tends by its very presence to
12 create a positive relief feature, it is positive because
13 the ice grows and heaves it up, and this, when associa-
14 ted with those slump scars, aids in its recognition.

15 In the Mackenzie Valley ice
16 veins and lenses are particularly abundant in lake
17 sediments, discussed earlier by Dr. Fyles. The ice in
18 these lake sediments tends to occur in a distinctive
19 3-dimensional articulate pattern very much like the
20 cement in a brickwork system, and Dr. Fyles showed a
21 land slide on the left bank of the Mackenzie down-
22 stream towards Fort Simpson. There are a number of land
23 slides which have occurred, or slumps in this ice
24 ridge of lake clays,

25 Permafrost conditions in the
26 Mackenzie Delta are quite unlike those of the rest of
27 the Mackenzie Valley. About 5,000 years ago the Mac-
28 kenzie Delta was a large estuary, 100 or more feet in
29 depth and the estuary probably extended south to
30 Arctic Red River. As the Mackenzie River discharged

J.R. McKay
In Chief

1 sediment into the estuary it built the present Macken-
2 zie Delta. The Mackenzie River is still building its
3 delta upward and seaward. At times of flooding, as in
4 1961 and 1973, much of the delta was under water,
5 perhaps 80 or 90% of the delta was under water, sediment
6 is laid down then on the flood plain of the river.

7 As the majority of the larger
8 lakes and channels in the delta do not freeze to the
9 bottom in winter, permafrost in the delta is perforated
10 with hundreds if not thousands of unfrozen and inter-
11 connected chimneys and conduits like the voids in
12 sponge rubber. That is perma frost in the Mackenzie
13 Delta is not continuous, but is just like voids in
14 sponge rubber, it is here and it is not in the next
15 adjoining place. So there will be no permafrost in
16 general beneath large lakes like that, or beneath
17 channels, but there will be perma frost below the land
18 areas. Consequently, when channels shift and lakes
19 become enfilled, permafrost is thawed at one site and
20 it grows at another.

21 Permafrost in the delta is
22 commonly less than 400 feet in thickness. I don't think
23 there are any records of permafrost more than 400 feet
24 in thickness in the delta; there could be in the southern
25 part but to my knowledge not in the north. Whereas
26 permafrost depths exceeding 1,000 feet up to 1,500
27 feet, perhaps more, occur in the higher terrain on
28 either side, so there is quite a contrast between the
29 delta and the adjacent terrain.

30 THE COMMISSIONER: Dr. McKay,

J.R. McKay
In Chief

1 in the delta, at what depth do you on the average
2 usually encounter permafrost?

3 A You're thinking of the
4 bottom of permafrost or the top of permafrost?

5 Q The top.

6 A The top. In the areas
7 underlain by trees like this, it would be of the order
8 of a foot and a half to three feet, depending upon the
9 micro deposits there. In the sandy areas or the point
10 bars it could be as much as three feet, four feet even.

11 Q And then extending to a
12 depth of up to 400 feet?

13 A That's right, sir. Down
14 in here, this is not a big land area but it could go
15 down maybe here to 350 feet, and it would cut down under-
16 neath like that.

17 THE COMMISSIONER: Thank you.

30

A Although permafrost in the Mackenzie Delta is going downwards in a substantial proportion of the land area, it is also going upwards through most of the same area and thus in two opposite directions at the same time. The upward growth results from flooding of the Delta and the accumulation of organic matter. This means that the active layer is thickened by the accretion of material (that is, sediment and organic material) so the permafrost surface will rise upwards by a like amount. This is an insight schematic diagram of permafrost over a long period of time, shall we say a thousand years. This is past. That is present. On the vertical scale there that is 300 feet, 200, 100 and zero. If we go back some time in the past to this position, we would have a lake, as the lake shows and the lake bottom is built above river level, permafrost starts to build downwards and this is the downward growth curve of permafrost.

At the same time sediment is being laid on the flood plain of the river and the flood plain is being built upwards, so that is the surface in here. So we have permafrost going upwards here and downwards at the bottom. As the upward permafrost surface rises it will incorporate within it, both the sediment and ice lenses at the bottom of the active layer, that is as more sediment is laid down, the permafrost surface rises. Therefore, if half the volume of the active layer is lens ice then an addition of five feet of sediment will

J.R. McKay
In Chief

1 result in an upward rise of the ground surface by
2 ten feet of which half is soil and half is ice.

3 Incidentally this is the
4 ice-soil ratio for the upper ten feet in the Aklavik
5 area and it was measured in 1954 and was one of the
6 reasons of course why Aklavik was not as suitable
7 a sight for the development of a northern town as
8 Inuvik.

9 The slide shows an eroded
10 river bank with a spruce tree near a ranger station
11 in the Mackenzie Delta. The survey rod in the
12 foreground is 4.5 feet long. When the spruce tree
13 commenced growth the ground surface was below the
14 bottom of the rod. As sedimentation proceeded the
15 permafrost surface rose and the spruce tree was able
16 to maintain growth by sending out adminitous roots
17 ^{rising} into the/active layer. That is, the tree started
18 growth when the ground surface was down here. That
19 is about six or eight inches in diameter. As the
20 permafrost surface has been agraded upwards in
21 response to sedimentation, the tree has sent out
22 lateral roots.

23 Clearly, permafrost has
24 agraded upwards a minimum of 4.5 feet in the lifetime
25 of this spruce tree. Therefore, at sites like this,
26 permafrost is growing both downwards and upwards and
27 the resulting ground ice in a single vertical section
28 will vary in both age and origin. The permafrost and
29 ground ice of the Mackenzie Delta then result from
30 present conditions which are quite distinct from the

1 past conditions when permafrost grew elsewhere in
2 the western Arctic Coast. For example, no mass of
3 icy sections are known to have formed in the Mackenzie
4 Delta. In contrast to such growth in the older, in
5 the nearby, higher areas.

6 Natural disturbances. In
7 permafrost areas where the ice content is high, the
8 melting of ground ice frequently results in a depres-
9 sion formed by subsidence. A lake which originates--
10 which occupies such a depression is known as a
11 thermokarst lake. The term thermokarst is derived
12 from thermal and karst, K.A.R.S.T. The term "karst"
13 refers to a distinctive type of landform for a
14 solution in limestone produces depressions, caves
15 and so forth, and Dr. Fyles showed us Oval lake
16 near Norman Wells, which he mentioned was formed by
17 solution of limestone. This is a karst feature,
18 thermokarst is not solution by limestone, but
19 subsidence by the melting of ground ice to produce
20 depressions.

21 In the Arctic a thermokarst
22 feature is caused by the melting of ground ice.
23 Thermokarst lakes are abundant in the Mackenzie Valley
24 and western Arctic Coast. I would presume if a
25 person were to make a count of them, they would
26 number in the many, many thousands.

27 The slide shows a 1935
28 oblique air photo of the coast 15 miles southwest of
29 Tuktoyaktuk. Lakes A and B are thermokarst lakes
30 about five feet deep. The lake bases were created

1 by the melting of ground ice. The shoreline
2 possessions in 1935, 1950 and 1971 are so marked.
3 The '50 and '71 positions are from air photos.
4 From 1935 to 1971 the coast retreated at an average
5 rate of 30 to 40 feet a year for a total distance
6 of 1,000 to 1,500 feet. The rapid coastal retreat
7 has resulted solely because the upper 15 feet
8 of the ground is ice rich. Where the coast is
9 only pore ice, as at the top right hand corner,
10 coastal retreats since 1935 is hardly 50 feet. There
11 is a contrast of about 50 feet on the top to
12 a 1,000; 1,500 feet since 1935.

13 The next slide will show the
14 coast for 1971. Please note first that in 1935 lakes
15 A and B were, well inland. This slide shows the
16 coast as it was in 1971, which is there, in 1974 the
17 coast was up in there. Note that lakes A and B have
18 now drained. The arrows in lake B point to three
19 pingos have grown up since 1950. Permafrost is
20 about 1,500 feet deep beneath the land areas, that
21 is beneath these areas, an estimate of permafrost
22 is of the order of 1,500 feet, therefore, it is obvious
23 that at the 1935 seacoast position, which was down
24 in here, permafrost about 1,500 feet thick is now
25 covered by the sea and there is off shore permafrost
26 caused by coastal retreat.

27 We should not get the
28 false impression that this example is typical of
29 the rate of coastal retreat, but it is a well document-
30 ed case, selected to illustrate a common method of
how off shore permafrost can originate.

1 In many areas surface distur-
2 bances to the active layer, whether by removal
3 of vegetation, burning or heavy rainfall can cause
4 thermokarst subsidence and thermalerosion. In mid
5 August 1968 forest and tundra fires burned extensive
6 areas in the lower Mackenzie Valley. Fires came
7 quite near to Inuvik. Here is a burnt area
8 two miles from Inuvik. It is between Inuvik and the
9 airport on the north side of the road. The
10 stakes there were driven down to the frost table
11 a few hours after the fires had burned the site
12 in 1968. The original vegetation cover of
13 mosses, lichens, etc, has burnt off, but the fire
14 swept by so quickly that the ground beneath never
15 warmed up.

16 This photograph was taken
17 in 1969 and vegetation was already becoming re-es-
18 tablished and we can see that fireweed is coming up.

19 The next slide is taken from
20 the same spot in 1972 and for identification we
21 could pick out that tree. This is taken in 1972,
22 two years later. Note the lush three foot vegetation
23 cover which has replaced the original ground vegeta-
24 tion mat.

25 Now, let us compare the effect-
26 iveness of the two vegetation types, that is the
27 original and the replaced vegetation, in controlling
28 thaw depths. This slide shows the thickness of the
29 active layer under the original vegetation cover
30 at the time of that 1968 fire and the subsequent

J.R. McKay
In Chief

1 changes until last summer in 1974. The ground
2 surface is at the top, one foot, two feet, three
3 feet, 68, 70, 72, 74. In 1968 the depth of
4 the active layer was 1.6 feet. In '69 when the
5 first photograph was taken, in there about 2-1/2,
6 '70, '71, '72 when the second photograph was taken,
7 about 3.3 feet.

8 We see that the active layer
9 thickness continued to increase every year from
10 1968 to 1973, a period of five years after the
11 fire. As there was very little change between 1973
12 and 1974 we can infer that the active layer is now
13 stablized in response to the present vegetation
14 cover. Although the rapid re-establishment of
15 vegetation can prevent or minimize surface erosion,
16 the active layer thickness obviously can continue
17 to increase. The long lag effect which was five
18 years resulted from the high ice content soil at the t
19 top of permafrost. It takes a long time for ice to
20 thaw at depth. Or if we put it another way, that
21 if this sight had been in sand, it would become
22 stabilized probably within the first year.

23 It may be instructive to
24 speculate on future changes to the active layer.
25 Most likely, in a few years, perhaps beginning even
26 this summer, 1975, the active layer will begin to
27 thin and the upper permafrost surface will rise.
28 The chances are this curve will begin to rise.
29 As the upper permafrost surface rises, the segregated
30 ice at the very bottom of the active layer will

J.R. McKay
In Chief

1 become incorporated into the top of permafrost.
2 The ground surface will then rise by an amount equal
3 to the segregated ice incorporated into the rising
4 permafrost surface. This is in direct parallel
5 to sedimentation in the Mackenzie Delta.

6 A ground surface rise of a
7 foot or more is quite probable. This type of res-
8 ponse where the active layer is first thickened and
9 then thinned, has been going on for thousands of
10 years and that is the basic reason why the upper
11 part of permafrost is often so ice rich.

In Chief

The thermal explanation for a thickening of the active layer is as follows. When the vegetation cover is destroyed, as by a fire, the bare ground gets hotter in summer than it did beneath the pre-existing vegetation cover. We know very well that if we take grass from the lawn and measure the ground temperature and remove the grass, have bare soil, the bare soil will become warmer. What happens then is that this was the maximum summer temperature under the original vegetation; by removal of the original vegetation, the maximum summer temperature is higher, this shifts this curve from there to there, by shifting it the active layer is thickened. This then shifts the mean angle of temperature by that amount. The essence is that the winter temperature can remain the same, but if the summer temperature increases, the depth of thaw then will increase and there will be a shift in the mean annual temperature.

The increase in thickness of the active layer can be estimated fairly accurately from data on soil type and the time lag from the ice content at the top of permafrost. Off-shore permafrost. Permafrost occurs not only in land areas but probably over large off-shore areas of the Beaufort Sea. Some of the off-shore permafrost is merely land permafrost which has been inundated as the shoreline has been eroded back as we saw earlier in the example of coastal retreat in the section south west of Tuk where we have had 1,000 feet of erosion since 1935, and we now have off-shore permafrost

J.R. McKay
In Chief

1 1,000 feet off-shore.

2 When glaciers covered large
3 land areas, world wide sea level was lower; and when
4 glaciers melted and water was returned to the sea,
5 world wide sea level rose. The world wide sea level
6 changes are shown diagrammatically in these slides, that
7 is here we are in the present, 20,000, 40,000, 60,000,
8 80,000, 100,000 years ago. Here is present sea level,
9 a depth of minus 100, minus 200, minus 300, and minus
10 400 feet. So this curve represents the approximate sea
11 level curve going back in time.

12 For example, a site now
13 50 feet below sea level along the horizontal line
14 would have been dry land approximately 60,000 years
15 ago. There, it's just above, probably near the shore-
16 line. About 8,000 years ago the site would have been
17 flooded by a rise of the sea, and Dr. Fyles gave us
18 data on the retreat of glaciers in the coastal area. So
19 that that site would have remained as dry land from
20 about there to about there, a period of about 50,000
21 years. In the Beaufort Sea area, long exposure of the
22 land would have resulted in the growth of permafrost.
23 Rough computations show that it could have grown to
24 a depth of perhaps 500 to 1,000 feet or more, if there
25 was no permafrost to start with.

26 However, the sea level rose
27 and the land was covered by cold sea water. As Arctic
28 sea water may have a temperature of minus 1 Celsius or
29 lower, because of its salinity obviously it does not
30 freeze at zero and it can be at a temperature below

J.R. McKay
In Chief

1 zero, a marine transgression of such cold sea water
2 will still perserve permafrost because it cannot melt
3 at the top. The only way it can melt is at the bottom,
4 and it would take at least 20,000 years for thick perma-
5 frost of 1,000 feet to melt upwards from the bottom.

6
7 Several years ago permafrost
8 was recounted in some drill-holes put in by industry in
9 the southern Beaufort Sea. Each dot is one such site.
10 For location then there is Inuvik, and this is the
11 Yukon-Alaskan border. The next slide --

12 THE COMMISSIONER: Excuse me,
13 Dr. McKay. Did you say that permafrost was encountered
14 at each of those sites?

15 A Yes sir. The next
16 slide will show ice samples brought up from the depth
17 of 30 feet below sea bottom where the water depth was
18 40 feet. That is from this site off the north end of
19 Richards Island. Here are ice samples from permafrost
20 which grew, presumably when the area was dry land, and
21 from here to here is one inch, so we see that those
22 samples are slightly over an inch in diameter and there
23 is very little doubt but that in the southern Beaufort
24 Sea there is permafrost under the sea floor of presum-
25 ably identical in most characteristics to permafrost
26 under the land. This is surmised but it seems to be
27 a fairly reasonable one.

28 Q And that would be so
29 with respect to the depth at which you would encounter
30 it, at the top and the bottom?

A Those wouldn't, sir.

J.R. McKay
In Chief

But in the case of the coastal retreat at Tuktoyaktuk the sea water there is Mackenzie River water coming in off Tuk, and the mean annual temperature of the Mackenzie River water is above freezing, so what will presumably happen at that site -- and we have done some studies -- is that the upper permafrost surface will thaw downwards because of the warm Mackenzie water, it will go down fairly rapidly, the bottom will go up very slowly, the maximum rate is about an inch a year, it cannot exceed that. So that in the Kugmallit Bay area, permafrost is down maybe 50 or 100 or more feet in depth. But if we get westward towards Herschel Island, where we are under the influence of marine water, then presumably permafrost is close to the surface but there's a complicating factor that the pore water in the sediments can be saline so that it may not have the consistency of hard frozen ground, but definitionally it is permafrost.

Q I see, thank you.

A Climatic change. Superimposed upon the ever-changing physical landscape there have been major climatic fluctuations. As permafrost is climatically induced the distribution of permafrost has likewise fluctuated in response to climatic change. There is abundant climatic evidence from long-term air temperature data to show that temperatures in the northern hemisphere warmed from about 1850 to 1950, with a subsequent cooling trend from roughly about 1950. As the ground surface gradually warmed, from about 1850 to 1950, the response to the rise in air temperature was propagated downwards into the ground. The record

J.R. McKav
In Chief

1 since 1850 is now preserved in the temperature of the
2 drill holes. This slide shows temperatures measured
3 by the United States geological survey for Point
4 Barrow, Alaska; similar data is available for Cape Simpson
5 and Cape Thompson. The 1950 curve is shown by the
6 red line. The 1960 curve by the green line. You have
7 then, down in here, depth in feet, 500 feet, 1000 feet,
8 across the top temperatures zero or 32, minus 2, minus
9 4, minus 6, minus 8, minus 10, minus 12. The 1950
10 curve for Barrow is this curve in there. It goes
11 along there from minus 8, follows this blue line and
12 it straightens out and goes down and there is the bottom
13 of permafrost at about 1,300 feet.

14 The 1960 curve is shown by
15 the green line which is this line in here, it moved
16 from 1950 to that position, a temperature of minus 9,
17 it moved there and then that is the curve that goes
18 does there.

19 If we had the 1970 curve,
20 which we do not have, it tends, I believe, off in there,
21 but I am not sure.

22 The interpretation is as
23 follows. The longterm average temperature as measured
24 over thousands of years is shown by these straight
25 lines. This is the long-term temperature in the area,
26 and projected up, it hits a temperature of minus 12.
27 In 1850 the mean annual ground temperature is estimated
28 at Barrow at about minus 12 degrees Centigrade or 10
29 degrees Fahrenheit. Then in 1950 which is a long-
30 term average, this would be, it is estimated, the

J.R. McKay
In Chief

1 temperature increase with depth. From 1850 to 1950
2 the ground surface warmed by four degrees, from minus
3 12 to minus 8. In other words, the ground surface
4 warmed up like that, and it swung ! this temperature
5 curve, it dragged it along with it, but since it takes
6 time for temperature waves to propogate down, there
7 is a lag with depth. So it warmed four degrees.

8 From 1950 to 1960 the ground
9 cooled one degree, which is this. A similar warming
10 and cooling trend is evident in the Mackenzie Valley.
11 Although the temperature record is not as detailed as
12 for Barrow, Alaska, the temperature records along the
13 Yukon coast and the Mackenzie Delta show a temperature
14 inversion with depth. It gets colder instead of getting
15 warmer, as it should. At Norman Wells there are half
16 a dozen curves which match this almost identically,
17 like that. If you go up to Cornwallis Island you
18 pick up the same thing. Melville Island, Ottawa,
19 Winnipeg, Kapaskasing, Hurst and the Maritimes, a
20 consistent trend, the trend is there, the actual amount
21 varies very slightly.

22 Studies by Dr. A.S. Judge of
23 the Department of Energy, Mines & Resources, show that
24 the temperature at Fort Providence about 100 years ago
25 was minus 2 Celsius, whereas now it is above zero, a
26 temperature change of very roughly three degrees.
27 That is Fort Providence had permafrost 100 years ago
28 and it has since thawed. The estimate of Dr. Judge is
29 that permafrost 100 years ago at Providence was probably
30 of the order of 100 feet in thickness, and that has since

J.R. McKay
In Chief

1 disappeared. Air temperature records for Fort
2 Simpson show that the mean annual air temperature has
3 decreased probably three degrees or more since 1950 ,
4 and a nearly equal drop in ground temperatures would
5 be expected. This is a winter cooling effect, not a
6 summer. It extends from Fort McPherson all the way down
7 to Fort Smith; the Delta is a consistent trend.

8 Now, if we then look at that
9 three degree cooling and look at our present ground
10 temperatures, along the coast here they are minus
11 8 to minus 9. In 1850 the temperatures there were
12 probably around minus 12. In 1850 Tuk would have had
13 a temperature, let's say, of Sachs Harbour.

14 In 1850, down in here the
15 temperatures in here, say Good Hope, would have a
16 temperature of Inuvik, and Yellowknife would have had
17 temperatures like that at Norman Wells. So that the
18 change has been quite substantial.

19 If we then look at the distri-
20 bution of permafrost as it might have been 100 years
21 ago, I have drawn the 1850 limit down here as the
22 southernmost limit that one would expect.
23

J.R. McKay
In Chief

1 I think actually it probably was higher. But irrespec-
2 tive, I think we can say with fair confidence that
3 100 years ago permafrost was not where it is now, the
4 boundary. 100 years ago the boundary of continuous
5 permafrost was down in there. That is the normal case
6 for the Mackenzie Valley, not the abnormal. Then these
7 boundaries moved northward, that is the present estimated
8 boundary of continuous permafrost, but that is probably
9 slightly off.

10 In other words, the boundary
11 of continuous permafrost moved northward; it meant
12 that large areas of permafrost in here were thawed
13 in the warming period from 1850 to 1950 and as a result
14 of present trends permafrost is without any doubt, I
15 think, growing in some areas in here. As a rough
16 estimate, I would say 20 to 30 feet of permafrost
17 has grown in some areas.

18 In the past 100 years then
19 we can be reasonably confident although not certain,
20 in stating that there have been major changes in the
21 thickness of the active layer, in the rapidity of down-
22 slope soil movement, in the development of permafrost
23 lakes, in the formation of ice wedges, and in the
24 disappearance and re-growth of permafrost. The effect
25 of such changes would be large in the southern part of
26 the Mackenzie Valley where permafrost is thin, and
27 minimal in the north where permafrost is thick. That
28 is the area most affected by climatic change would
29 be down in here where permafrost is thin, up in the
30 north I do not think it would have made a great deal of

J.R. McKay
In Chief

1 difference. Consequently, permafrost is not static
2 in the Mackenzie Valley because it responds to an ever-
3 changing climate.

4 In conclusion, permafrost in
5 the Mackenzie Valley and Northern Yukon is diverse in
6 its age, origin, distribution and ice content. Along
7 the Yukon coast some permafrost pre-dates the last
8 glacier advance and it is upwards of 40,000 years old.
9 By way of contrast, some permafrost has probably grown
10 in the Southern Mackenzie Valley in the past 20 years
11 as a result of recent climatic change. Some of the
12 ice in permafrost is pore ice formed by the freezing of
13 interspacial pore water. Some is segregated ice,
14 accreted by the addition of ground water at the bottom
15 of permafrost. Some is ice wedge ice derived from
16 surface water.

17 Such ice types vary in verti-
18 cal and horizontal distribution, and each type gives
19 a different response to physical and thermal distur-
20 bance. Natural disturbances or changes such as
21 thermal erosion, permafrost subsidence, ice ridge
22 gulleying, lake drainage, slumping, fire, coastal
23 erosion, marine inundation, and climatic change have
24 been taking place for as long as permafrost has been
25 in existence.

26 Natural disturbances are
27 the surrogates for artificial disturbances and we have
28 much to learn from them. In this overview of permafrost
29 attention has been deliberately focused on ground ice
30 and its problems. In doing so, we should also remember

J.R. McKay
In Chief

1 that there are very extensive permafrost areas which
2 have so little ice that the response to a change is
3 essentially similar to the response of a non-permafrost
4 area to the same change in Southern Canada.

5 THE COMMISSIONER: Thank you
6 very much, Dr. McKay. We are in your debt.

7 (WITNESS ASIDE)

8 MR. SCOTT: Mr. Commissioner,
9 could I suggest that we should adjourn now and come
10 back at one o'clock?

11 THE COMMISSIONER: All right,
12 we'll adjourn until one o'clock.

1 (PROCEEDINGS RESUMED AT 1 P.M.)

2 MR. SCOTT: Mr. Commissioner,
3 at the beginning this morning Mr. Anthony made some
4 requests of you, and I suspect of me, and I asked if I
5 could consider them and respond. I've now had an
6 opportunity of looking at a praecipe of what he said. He
7 really asked two questions, as I understand it from his
8 words:

- 9 (1) Whether Commission counsel could inform him and his
10 colleagues that the Department of Environment wit-
11 nesses who have relevant testimony would be made
12 available to the Inquiry, and
13 (2) He asked you to instruct Commission counsel to
14 communicate with the Minister of the Environment
15 to determine that Department of Environment experts
16 who have relevant evidence would be made available
17 at government expense to present their evidence.

18 Now let me deal with the first question or the
19 second question, is it possible for us to provide an
20 assurance that Department of Environment experts who
21 have relevant testimony to give will be available at
22 government expense?

23 We have now, since this morning,
24 obtained assurances from the Department of Indian
25 Affairs & Northern Development that any expert witness
26 in the Public Service of Canada who has relevant evidence
27 to give to the Inquiry and who is called to testify
28 will be available at government expense to present their
29 evidence; and government expense, just so it is clear,
30 means that travel and associated expenses will be paid

1 and the payment of the witnesses' salary will continue
2 while of course they are engaged in giving evidence at
3 the Inquiry. So I think that that assurance complies
4 fully with the second request that my friend made.

5 The first request, can Commis-
6 sion counsel inform us that the Department of Environ-
7 ment witnesses who have relevant testimony will be made
8 available to the Inquiry? I have considered that and
9 in the course of considering it I have seen a press
10 report which was in the "Globe & Mail" of February 28,
11 1975, and which, for the purposes of this answer, I assume
12 to be accurate. In that press report the Minister of
13 the Environment, Madam Sauvé was reported to have
14 decided to put department experts at the disposal of
15 the Inquiry and to open all doors on environmental
16 information and expert knowledge held by the Department.
17 As a result of that press report, which I assume to be
18 correct, I propose today to communicate with the
19 Minister of the Environment to accept that invitation
20 on behalf of the Inquiry and to consider ways in which
21 that information and knowledge can promptly be made
22 available. At the same time and in the same way I
23 intend to communicate with the Minister of Indian
24 Affairs & Northern Development, and I hope that after
25 that communication has gone forward I will be able to
26 report in public to the Inquiry about its results
27 shortly. I think that second question therefore is
28 responded to in that way. I will make the enquiry
29 requested and I will report to the Commission.

30 THE COMMISSIONER: So I take

1 it we can leave that matter there for the time being,
2 Mr. Scott.

1 MR. ANTHONY: Mr. Commissioner,
2 in view of the -- our involvement in this I would
3 just like to briefly say that I welcome the comments
4 of Commission Council in respect to the actions to be
5 taken and I would urge the Government to respond
6 favourably to these directives and I would hope that
7 in carrying out of the action that has started today,
8 that we will be able to co-operate with the govern-
9 ment and with this Commission in ensuring that these
10 issues are brought before the Inquiry and I look with
11 confidence in the rapid resolution of this matter, in
12 order that this hearing can proceed in the prompt
13 fashion that we all desire.

14 Thank you.

15 MR. SCOTT: Mr. Commissioner,
16 the next overview witness is Professor Michael Church
17 and his subject generally which he will introduce is
18 an overview of hydrology in northern rivers.

19 Mr. Church.

20 MICHAEL ANTHONY CHURCH, sworn.

21 THE SECRETARY: Please state
22 your full name.

23 A Michael Anthony Church.

24 DIRECT EXAMINATION BY MR. SCOTT:

25 Q Professor Church, I under-
26 stand that you are an assistant professor of geography
27 at the University of British Columbia, is that
28 correct?

29 A Yes, that is correct.

30 Q And can you tell the

M.A. Church
In Chief

1 Commission where your university training was taken
2 and in what general subjects.

3 A Yes, my undergraduate
4 training was at the University of Toronto in the
5 subject of geography, particular attention to physical
6 geography, and after that I did graduate studies at the
7 University of British Columbia with specialization
8 in geomorphology and I was particularly interested in
9 the geomorphology of northern lands.

10 Q For my benefit if not
11 for the benefit of anybody else, what is geomorphology?

12 A Geomorphology is the
13 study of the form and processes that change the form
14 of the surface of the earth. So it is the study of
15 erosion, sedimentation, river activity, slope activity
16 and the like.

17 Q Yes, well now, Professor
18 Church, have you been engaged from time to time in
19 any field work in this specialty?

20 A Yes, I have. I have spent
21 a total of ten years in the study of geomorphology
22 in northern Canada. I have spent eight seasons or
23 parts thereof in Eastern Arctic studying glaciers, riv-
24 ers and river sedimentation, in that part of the world
25 and part or all of four seasons in the northwestern
26 part of Canada and adjacent portions of Alaska engaged
27 in similar pursuits.

28 Q Yes. Well now, I under-
29 stand that in 1971 and 1972 you were engaged doing
30 work for the Mackenzie Valley Pipeline Research

1 Company Limited. What sort of work was that?

2 A That was a recon-
3 naissance of hydrology and river conditions along the
4 route of a proposed oil pipeline from Prudhoe Bay to
5 Edmonton, Alberta, which was routed via the Mackenzie
6 Valley.

7 Q Yes, I see.

8 Well now, Professor Church,
9 I would ask you to carry on as the other overview
10 witnesses have. Please.

11 A Thank you.

12 THE COMMISSIONER: Just a
13 moment, Mr. Church. Mr. Genest, if you or any other
14 member of counsel has any difficulty hearing just
15 move your chair over here.

16 MR. GENEST: These interventions
17 of yours please me. The people behind me stop talking
18 and I can hear.

19 THE COMMISSIONER: Mr. Church,
20 just one question before you start. You said that
21 you had been working with the Mackenzie Valley Research
22 Company in connection with a proposed oil pipeline
23 from Prudhoe bay to Edmonton. During what period
24 of time was it that you were engaged in working with
25 that company?

26 A I began this investiga-
27 tion in May of 1971 and my investigations for them were
28 complete by September 1972. My findings were incor-
29 porated in two reports that were printed by the company
30 and released to interested parties, including

1 Government parties, as part of their reconnaissance
2 to inquire into the feasibility of such a line. I
3 understand that that work has not gone any further and
4 finished at that time.

5 THE COMMISSIONER: Thank
6 you. Well, carry on in your own way.

7 A Thank you.

8 Well, Mr. Commissioner and
9 ladies and gentlemen, I have been asked to discuss
10 aspects of hydrology and rivers in Northwestern
11 Canada. Running water on the land is important both
12 as one of the major agencies that erodes and shapes
13 the surface of the land and of course it is a vital
14 material for the support of life.

15 In addition in the North,
16 frozen water produces special and important seasonal
17 and long term effects, some of which we heard about
18 this morning when my colleague Professor McKay
19 discussed some aspects of water under the surface.
20 During my remarks I want to add to this by making
21 some discussion about the effects of surface ice as
22 well.

23 Can I have the slide projectors
24 please.

25 The slide on the right. -- I
26 would like to begin by indicating that the terrestrial
27 phase of the surface of the land of the so-called
28 hydrological cycle which describes the movement of
29 water at or near the earth's surface, can be simply
30 characterised as on the right here by the division

M.A. Church
In Chief

1 of precipitation inputs and in this diagram the tri-
2 angles indicate inputs and outputs of water and the
3 square boxes indicate major storage points and the
4 diamonds indicate points at which major divisions in
5 the flow of water occur.

6 So here, precipitation is
7 divided into two streams, one of which constitutes
8 direct run off on the surface of the land when rainfall
9 occurs on the surface for example and the other of
10 which consists of water that percolates into the
11 surface of the ground and remains in the soil as
12 soil moisture or as ground water. Some of the moisture
13 which percolates into the surface of the ground accor-
14 ding to local climatic conditions may subsequently
15 be evaporated directly from a moist soil surface
16 or much more important, much of this moisture is taken
17 up by plants and transpired in the course of plant
18 activity.

19 Some of it may subsequently
20 seep back to the surface in springs and join the direct
21 runoff on the surface, where it passes via lakes, bogs
22 and river channels, ultimately in runoff to the sea.
23 So in sum, in that portion of the hydrological
24 cycle in which we are interested, precipitation inputs
25 find their way either to evaporation and transpiration
26 or to runoff from the surface of the land and we will
27 be particularly interested in the conditions of runoff.

28 Well, in Northern Canada, this
29 simple picture of the hydrological cycle is somewhat
30 modified by several features that are related to the

1 extreme thermal conditions including the ground
2 thermal conditions which Drs. Fyles and McKay
3 discussed this morning, so that processes leading
4 to runoff are somewhat different and this modified
5 diagram on this side illustrates some of these modi-
6 fications.

7 First of all, important
8 everywhere in Canada, is the possibility that when
9 precipitation falls, temperature conditions will be
10 below freezing and so the precipitation will fall as
11 snow and be passed into snow storage, thence to remain
12 on the surface of the land until in the spring, local
13 warming of the atmosphere produces snow melt when the
14 melt water becomes available for movement further on
15 through the hydrological cycle.

16 Some other important differ-
17 ences occur in the soil moisture term over here,
18 the ground thermal climate will determine whether on
19 a seasonal or as Dr. McKay described this morning,
20 on a long term basis, moisture may remain in frozen
21 form in the surface, or under the surface of the
22 ground as ice. And again, down here standing water
23 on the surface and water in river channels as well
24 may seasonally be frozen at the surface so that ice
25 cover forms on lakes and river channels and then in
26 the following spring melt returns this water to the
27 fluid form and it continues to move through the
28 terrestrial hydrological cycle.

29 So these major changes are
30 related -- or these major complications are related to

1 the extreme thermal conditions that we find in northern
2 Canada.

The most important of these effects, so far as short-term view of the hydrological cycle is concerned is the routing of precipitation to snow storage for much of the year. In Northern Canada it's 7 to 10 months' precipitation, depending on where one is and how long the winter and summer seasons are locally. 7 to 10 months/^{precipitation input}remains as snow in storage on the surface of the land and then it is all melted in a few weeks in the spring of the year. The hydrological effect of this is that 7 to 10 months' precipitation is re-distributed as if it had all occurred during that brief period of snow melt. So far as the movement of water on the surface of the land is concerned, it is as if all of that precipitation had appeared in a few weeks instead of . over a period of seven months or more.

Most northern regions do experience a summer maximum of precipitation so that during this 7 or 8 or 9-month period of the year about one-half of the total annual precipitation falls, so about one-half of the total annual precipitation is effectively stored and then released or run off from the surface during a short period in spring. On this map, which summarizes the annual precipitation in Northern Canada, the dotted contours indicate the proportion that falls as snow. In the Mackenzie region, which is the study of main interest, between 40 and about 50%, 45 to 50%, more in the mountains of the total annual precipitation occurs as snow.

So the effect of snow storage

M.A. Church
In Chief

1 in re-distributing precipitation input is the single
2 most important feature of the modified hydrological
3 cycle in the north. The hydrological significance
4 of summer rainfall, the other half of the precipitation,
5 is largely tied up in the intensity with which individual
6 rainstorms may occur. Relatively warm air masses in
7 summer may carry a far larger amount of water vapor
8 than cold air masses of winter, so that when
9 meteorological conditions produce precipitation, it's
10 possible that far larger, far more intense precipitation
11 may occur than usually occurs in the winter.

12 One such intense summer
13 rainstorm was one that occurred in the Upper Keele and
14 Arctic Red River regions of the Mackenzie Mountains
15 west of Mackenzie River, on July 20 and 21, 1970. This
16 storm has been studied reasonably well. The slide
17 gives a meteorologist's estimate of the total precipi-
18 tation that occurred during the storm, and near the
19 centre of the storm over a period of -- I believe
20 the summarization is for the period, July 18 to
21 July 21 -- during 20 and 21 July most precipitation
22 fell, and the total was five inches or greater precip-
23 itation in this central region, and less as you move
24 farther away.

25 I should like to emphasize
26 that the relative lack of observing stations in the
27 region, major climatological stations are indicated
28 and they all fall nicely around the central region
29 of the storm, I'm afraid, make it rather difficult to
30 be sure of this data. So this can at best be seen as

M.A. Church
In Chief

1 approximation of conditions that occurred.

2 By comparison with data of
3 other storms experienced at the Weather Stations in the
4 region, it was decided that the return period for a
5 storm of this size -- that is to say the mean time
6 between recurrences of a storm of this intensity and
7 magnitude -- should be of order, 10 to 15 years. This
8 particular storm caused extensive flood damage on
9 several rivers, particularly upper reaches of the
10 Arctic Red and Mountain and Rivers which -- the
11 Keele River down here -- which drain to the Mackenzie,
12 and an examination of damaged trees along the upper
13 reaches of these river courses led to the hydrological
14 estimate that the flood produced by this storm only
15 recurred once every 100 years or so, along these
16 rivers.

17 Now there's quite a discrep-
18 ancy between this estimate and the estimate of the
19 recurrence for a storm of this sort, based on the
20 meteorological studies. This might partly reflect
21 antecedent conditions. It may be that before this
22 particular storm arrived there was already quite a
23 lot of water stored on these water sheds, in the soil,
24 in ponds, and so most of the precipitation ran off,
25 whereas on other occasions a good deal of precipitation
26 would remain on the water sheds in storage. But I
27 think mainly this discrepancy is the result of the
28 geographic localization of the extreme effect of this
29 storm within a fairly small region -- but in absolute
30 terms it is not small, but it's fairly small by compari-

M.A. Church
In Chief

1 son with the density of the regular weather observation
2 network, and unfortunately, it's particularly centred
3 in this mountain region where there aren't many regular
4 observing stations.

5 So consequently, though
6 meteorological storms of this scale may recur in North-
7 western Canada with a frequency of a decade or so, in
8 each case the effects, the storm centre will perhaps
9 be located in a somewhat different geographic place and
10 so the most extreme effects of such a storm will occur
11 in a slightly different place than they occurred the
12 last time, and consequently only much more rarely are
13 the most extreme effects visited at one particular
14 place.

15 The lesson of this, and the
16 reason why I've described this event in some detail,
17 is that in hydrological work we must rely to a great
18 extent on available historical records of the sequence
19 of weather, of the sequences of run-off in the various
20 rivers, and the history of this storm and the results
21 of its analysis indicate that our observing networks
22 of Weather Stations -- and the same is true of our
23 Stream Gauging Stations in the north -- is sparse, too
24 sparse to be able to measure the full geographical
25 variability of events that occur. So we must be very
26 careful in interpreting the range of conditions that
27 can occur in Northwestern Canada from available records,
28 for we may not be seeing anything like the full range
29 of events that may occur, because of the sparse nature
30 of the measurement network.

M.A. Church
In Chief

1 The presence of permanently
2 frozen ground in the north, discussed by Dr.
3 McKay this morning, restricts exchanges between surface
4 water and sub-permafrost ground water, so that there is
5 a lot of standing water occurs on the surface as a
6 frequent result of this. As Dr. Fyles pointed out,
7 though much of the north constitutes climatic desert,
8 by classical standards, total precipitation is quite
9 light through much of the north, reduced evaporation in
10 the cold climate in the north and the restriction of
11 most water circulation to the near surface. The
12 possibility of deep percolation into the ground is
13 prevented by the presence of frost, so that only a few
14 restricted sites, such as on sandy ridges, do conditions
15 of physiological drought frequently occur, and that
16 most places on the surface in the north, there's an
17 abundance of water during the summer season of the
18 year when it's important for the growth of vegetation
19 and so on.

20 The chief contributions to
21 run-off in the rivers then come from seasonal snow melt
22 and seasonal rainfall by direct surface flow on the
23 surface -- that's down this line or this line -- or
24 as the result of flow through the shallow soil and then
25 back to the main line as delayed run-off, but not as the
26 result of deep percolation and then resurgences at
27 springs, deep springs. So run-off in much of the
28 north can be analyzed as a surface flow and soil flow
29 phenomenon, and deep ground water circulation need not
30 be considered as important.

M.A. Church
In Chief

1 In such circumstances, winter
2 flow in streams often becomes very small and most
3 small streams have no winter flow at all. On the
4 Arctic slope, this may be true even of sizeable drain-
5 age basins for in the winter the active layer freezes
6 seasonally, water within it is frozen, and no water
7 movement occurs and there is no seepage from deep
8 sub-permafrost sources.

9 This slide plots minimum
10 monthly discharges during the winter, normalized with
11 respect to drainage area against mean January tempera-
12 ture.

Those stations where there is no permafrost are generally in the upper right-hand portion of the diagram, indicating that there is considerable winter flows experienced. This is because ground water continues to feed small amounts of water into the river channel which flow off ^{year round}. In regions of discontinuous permafrost, winter flows are somewhat reduced, and in areas of continuous permafrost we have very low or zero winter flows on the whole.

The data base for northern run-off is shown on this diagram on the left. It's not a good data base, particularly when it's realized that many of the stations are on the main stem of Mackenzie River itself. The Mackenzie River is a very large river, whose run-off comes from extremely large area, and so the river effectively integrates the variable effects of run-off from many places. At one time a storm in this region or some storm in this region may introduce considerable water into the system; at another time a storm centred up here, perhaps might introduce considerable water into the system, but usually not from both places at the same time. The net result is that in one way and another the river maintains a fairly equitable flow, through all this local variability in run-off supply.

So once again, much of the regionally variable character of the hydrology of Northwestern Canada is lost from the available records. Before continuing, I'd like to point out that basic Stream-Gauging Stations are indicated by the small dots

M.A. Church
In Chief

1 and the larger ones. Those stations where in addition
2 sediment transport observations are made, have orange rings
3 around them, and those stations, primarily the same
4 ones again, where winter ice thickness observations
5 were made of the green ring outside that.

6 More unfortunate still from
7 the point of view of being able to study the character
8 of hydrology in the north is the fact that a number of
9 stations with more than five or ten years' worth of
10 records are even fewer than the number of stations
11 shown here, and they are virtually all on the main
12 stem of Mackenzie River or a few lake controlled
13 tributaries. The slide on the right shows the number of
14 stations with useful long-term records.

15 We have very little information
16 on a long-term basis from tributaries on either side of
17 Mackenzie River itself. Beyond research results of
18 short duration, there are almost no records from
19 small water sheds, and as I will try to show later
20 on, it's very often in small local areas, that most
21 extreme effects of particular hydrology events are visited.

22 The pattern of run-off in the
23 rivers can be categorized broadly on a regional basis.
24 Mr. Commissioner, some of the data on the slides I'm
25 about to show you come from rivers that are not within
26 the region of main interest. They are rivers, however,
27 all within Northern North America, and in each case I
28 believe the effects to be comparable with those you can
29 expect from rivers within the area of interest. The
30 reason for my choice is that to illustrate some of these

M.A. Church
In Chief

1 hydrological regimes there is simply no record avail-
2 able within the region of interest.

3 These two graphs show on a
4 seasonal basis what I call Arctic Nival Regime. Nival refers
5 to the dominance of the run-off regime by snow-melt
6 events in the spring, "nival" referring to snow-melt.
7 In these areas which are areas of continuous permafrost
8 there is little possibility for winter run-off and so
9 these streams are winter-dry, consequently these
10 graphs are restricted to the period, May to October.

11 The spring snow-melt flood is
12 apt to be the most severe one in rivers of this type
13 for the generally light peak intensities and low volumes
14 of summer rainfall are usual in the Arctic regions
15 where this regime type is found, in comparison with the
16 sub-Arctic, which we will look at in a minute.

17 In very small water sheds,
18 locally severe precipitation may occur in the summer
19 and floods in small water sheds may approach or
20 exceed in magnitude the effect of the snow melt flood.
21 So on this small river which actually is on Devon
22 Island in the Canadian/^{Arctic} Archipelago, some events in the
23 summer, the result of rainfall, appear quite important
24 in the run-off record; whereas in this large river, the
25 Colville River which drains part of the Alaskan north
26 slope and has a regime not much different from that
27 which we would expect on Firth River, for example,
28 on the Yukon north slope, the spring snow-melt event
29 is easily the most important.
30

M.A. Church
In Chief

1 An interesting feature of this
2 particular run-off regime is that in the spring run-off
3 usually commences over ice lying in the channel bed from
4 the previous autumn. Run-off must break through snow
5 drifts in the channel along the way.

6 In the sub-Arctic, generally
7 areas within the tree line, we have a sub-Arctic
8 Nival Regime. This is characterized by an important
9 snow-melt flood in the spring, here illustrated on
10 White Sand Creek, an east bank tributary of the
11 Mackenzie River. That photo was taken on May 10, 1973.
12 Then there are generally low levels of flow throughout
13 the summer period thereafter, but punctuated by periodic
14 rainstorm floods, and this is evident particularly on
15 this graph for Arctic Red River near Martin House.
16 Please note that this graph is based on a different
17 year length than this one here, January-December; in
18 this case, January through December, so run-off occurs,
19 peak run-off occurs at the proper time, despite the
20 changed axis.

21 The rainstorm floods of summer
22 may be more severe than the spring freshet on these
23 rivers, and we can see this on the Arctic Red case,
24 in this case the gauge was not operative part of the
25 spring snow-melt flood, but we can see that fairly
26 major summer rainstorm floods do occur. I can refer
27 you again to the July 20-21 storm that we looked at a
28 while ago, which was the most extreme hydrological
29 event that some of the rivers in this region, including
30 Arctic Red River, have experienced in many, many years.

M.A. Church
In Chief

1 That was not associated with snow melt.

2 These two slides further illus-
3 trate the importance of summer floods. They are two
4 views of a small creek opposite Rigley where about two
5 inches of rain occurred locally in 12 hours, in late
6 July of 1974. This view, showing the usual summer
7 conditions of the creek, is taken from the building
8 that's shown in the view on the right.

9 In the sub-Arctic Nival
10 Regime, small rivers are winter dry but large ones
11 may continue to flow under ice cover year-around.
12 Much of the base flow is derived from unfrozen gravel
13 along the channel, although deep springs do occur in
14 the mountains, in particular there are thermal springs
15 at several points in the Mackenzie Mountains and British
16 Mountains of the Northern Yukon. This sub-Arctic
17 Nival Regime type is particularly characteristic as
18 well of northward flowing rivers, such as Keele River,
19 Arctic Red River, whose headwaters may lie in discon-
20 tinuous permafrost country to the south, and where
21 there is a possibility for continued winter re-charge
22 of the river from deep ground water occurs.

23 I'll ask you to ignore this
24 top graph. I'm afraid these slides are doing double
25 duty and they've been used before in another context.

26 I wish to draw attention now
27 to what I call the Muskeg Regime which is important
28 in Northwestern Canada, as Dr. Fyles points out, there
29 are large areas of peat and muskeg landscape. This
30 regime type is also characteristic of lake controlled

M.A. Church
In Chief

1 drainage basins, in fact Kakisa River is lake controlled
2 as well as having a good deal of muskeg in its basin.

3 The view on the right is taken looking
4 toward Roche-qui-Trempe-a-l'Eau on Mackenzie River from
5 the north end of the Camsell Range, and shows typical
6 forest and muskeg at low level along the Mackenzie
7 Valley. Muskeg is intimately associated with poor
8 drainage. Because of the large water-retaining
9 capacity of the vegetation, as well of the direct
10 impediment of a run-off that is presented that Dr.
11 Fyles illustrated, flood peaks are strongly attenuated
12 in muskeg dominated water sheds.

13 In the Arctic, grassy or heathy
14 hummocked as well, as a result of
15 tundra, which is often/frost heave in the active layer,
16 similarly has the capacity to hold a great deal of
17 water and to therefore strongly attenuate flood peaks
18 of run-off so that much less abrupt run-off peaks
19 occur in rivers of this type than is common in the
20 two regime types that we've looked at earlier.
21
22
23
24
25
26
27
28
29
30

1 For the small watershed at
2 Ogotoruk Creek, which is actually in Arctic Alaska,
3 more peaked floods do occur including one major rain
4 storm flood shown here, but again, as I will demon-
5 strate in a moment, the effect is considerably damped
6 over other small watersheds of the type.

7 Lowland tundra with much
8 standing water on the surface, behaves similarly as
9 well, as a great deal of water can be stored on these
10 ponds and standing water places after precipitation
11 events. It does not run off immediately.

12 On these Arctic tundra water
13 sheds, if the sod mat is dry before a summer rain
14 storm occurs, a great deal of moisture can be stored
15 in this erstwhile dry sod mass or in hollows and ponds
16 on the surface, so that little runoff will occur.
17 On the other hand, if wet conditions precede a storm,
18 then there may not be nearly so much storage available
19 and then there may be a much more peaked run off, as
20 probably occurred in this particular case, for example,
21 it may have been a continually damp period, in addition
22 this is probably a pretty major storm.

23 Because of the importance then
24 of the antecedent condition, there is very variable
25 response of the small Arctic watersheds to reasonably
26 small storms. This is indicated here, where the
27 rainfall is plotted against the peak discharge
28 observed and the data is from Ogotoruk Creek. For
29 small storms a very variable response which depends
30 on how wet the watershed is before precipitation input

1 occurs. For large storms of course, which always
2 exceeds the storage capacity of the watershed then
3 a fairly predictable response begins to be ascertained.

4 It is interesting to compare
5 the response of these tundra, heath dominated water-
6 sheds with the response from barren watersheds, terrain
7 of this type which is common in the Mackenzie Mountains
8 to the west of the Mackenzie River, for example. And
9 this compares the storm response of Ogotoruk Creek
10 with the response of Twisty Creek, a small watershed
11 in the Mackenzie Mountains and superficially the
12 responses look similar except that for Ogotoruk Creek
13 the time axis for the storm runoff in the river is multiplied by
14 ten over that of Twisty Creek. This means then that
15 the rise of the flood wave and the decline are about
16 ten times longer for Ogotoruk Creek than for a
17 comparable condition at Twisty Creek on the barren
18 surface in the mountains. On this barren surface there
19 is not much place for moisture to be soaked up and
20 retained on the watershed, realizing the substrata is
21 frozen at a shallow depth as well, so not even the
22 soil provides much room.

23 It follows that for equal
24 precipitation inputs the flood peak will be much more
25 severe on a watershed of Twisty Creek site, -- or
26 Twisty Creek characteristic, I am sorry. On this
27 diagram, this characteristic has been disguised since
28 the runoff is normalized by dividing by the peak
29 discharge for the watershed in each case, so we have
30 a normalized scale of zero to one here.

1 The occurrence of ground water
2 in permafrost regions is something that I would like
3 to say a few words about. It is not essentially differ-
4 ent from its occurrence in general elsewhere. However
5 there are several important modifications that result
6 from the presence of frozen ground.

7 First of all, obviously in
8 frozen areas, water is rendered immobile as ice, so it
9 does not move. Permafrost is effectively an impermeable
10 barrier to water movement, so if there is permafrost
11 it increases the number of barriers to ground water
12 movement in the active layer. For example, in parti-
13 cular, ground water movements are often constrained
14 to the corresponding surface water catchments in
15 permafrost areas, since surface drainage divides usually
16 correspond with highpoints on the frost table under
17 the surface.

18 This is different from
19 conditions in the south where very frequently ground
20 water drainage does not correspond with surface drain-
21 age catchments, so that in the North in fact, hydro-
22 logical analysis is sometimes simplified by this fact.
23 We can treat each individual watershed as essentially
24 its own unit which receives precipitation and ultimately
25 either evaporates it or sees it pass out through the
26 stream channel that drains it.

27 In the south we cannot always
28 -- we frequently cannot assume this.

29 As well, permafrost can alter
30 water tables, that is the level below which standing

1 column occurs in the ground from normal configurations
2 and this may complicate the analysis of soil and
3 ground water. In areas with permafrost this becomes
4 a particularly complicated problem in the areas of
5 discontinuous permafrost. Where there is frost under
6 the surface, you may have a high water table perched on
7 top of that frost, where there is not frost, no permanently
8 frozen ground under the surface and you may have
9 effective drainage so that the underground water level
10 is a much greater depth.

11 The occurrence of ground
12 water is associated with riverflow in two ways.
13 First, it leads to the possibility of continued flow
14 through the winter as I have indicated in discussing
15 subarctic nival runoff regimes, and often this flow
16 may be below the channel bed through permeable gravels,
17 where the river bed remains unfrozen. Where springs
18 or seepages occur to the surface, massive accretions
19 of surface ice known as icings, one of which was
20 illustrated by Dr. Fyles, can develop during the winter
21 and I want to discuss icings later for they have
22 some important consequences for the stability of river
23 channels.

24 Turning now to look at the
25 rivers themselves, that carry the runoff we have been
26 discussing, the character of a river is determined
27 by several features, amongst which the following are
28 particularly important.

29 First of all, the imposed
30 run off. The river channel must be capable of passing

1 the water that arrives into the channel.

2 Secondly, the sediment load
3 that comes with this water from upstream is important
4 in determining the character of the channel. Hence,
5 geology, including the erodibility of bedrock and
6 unconsolidated materials in the upstream watershed
7 become important for these will determine the condition
8 of sediment supply.

9 Third, the particular bed
10 and bank materials through which the river is flowing
11 are important for these will help determine the
12 particular configuration and stability of the river
13 channel.

14 Fourth, the gradient down
15 which the river flows is an important factor in
16 determining the character of the river channel. This
17 gradient may be imposed by physiography or geology,
18 as when the river flows on bedrock that it cannot
19 easily erode, or the slope may be determined by the
20 river itself when it flows in its own deposits,
21 its own deposited sediment which we will call alluvium.

22 Since each of these factors
23 can change along the course of a river, bed and
24 bank materials may change, discharge commonly increases
25 downstream of course as tributary channels join a
26 main channel and the sediment delivered to the channel
27 changes accordingly. We can expect the character of
28 a river channel to change as you proceed downstream
29 along it. It is therefore prudent to characterise
30 individual lengths of a river channel or reaches

1 rather than to try and characterise or classify entire
2 rivers per se.

3 I will define a reach as
4 a length of river channel within which each of the
5 conditions that I have just mentioned remains substan-
6 tially unchanged, so discharge, sediment load, bed
7 and bank materials, and the gradient of the river
8 remains substantially unchanged and in these circum-
9 stances we can expect the channel to have the
10 same morphological character, the same features along
11 this length, clearly my conditions mean
12 that a reach will be restricted to a length say,
13 between important tributary junctions, for at that
14 point discharge will change as the tributary flow is
15 added.

16 What I am going to do now
17 is indicate to you several types of reaches that are
18 commonly encountered in rivers in Northwestern Canada.
19 Now, this is not meant to be an exhaustive classifica-
20 tion, nor do I mean to indicate that peculiarities of
21 particular reaches may not be very important, but in
22 the absence of much specific data about northern rivers,
23 I think that this is a useful way of generalizing a lot
24 of important pieces of information about the way that
25 rivers behave.

26 In the diagrams, the first of
27 which is on the left here, I would like in addition
28 to point out that the blue colour in the channel bed,
29 these are cross section diagrams of river channels, and
30 the blue colour is intended to indicate winter ice

1 conditions that are characteristic of these channel
2 types that I will discuss, whereas the red dotted lines
3 are intended to indicate characteristic summer frost
4 tables under these rivers, so I am trying to indicate
5 frost conditions around these river channels at the
6 same time.

7 Now this is inconsistent in
8 the sense that I am looking at summer frost conditions
9 and winter ice conditions, but it conveys useful
10 information on the one diagram. I have not commonly
11 shown water levels within these channel diagrams.

12 The first river type that we
13 can look at, using the character of bed and bank materials
14 as the primary criteria for classification, and
15 then river pattern as a secondary criterion, for these
16 are the two things about a river that we can see
17 right away when we go to visit it. We have to
18 wait and gather records to find out about the runoff
19 regime or the sediment transport, but we can see these
20 things right away so they are useful basis for the
21 classification.

22 First of all, we may look at
23 large gravel rivers, rivers flowing in gravel, cobble,
24 stoney channels.

25
26
27
28
29
30

M.A. Church
In Chief

The first type of pattern we'll look at is the so-called braided pattern, which is illustrated on the right by a reach on Mountain River just above the confluence with Gayna River. In this river type we see many channels, many individual channel segments which occur within a wide channel zone. So here is a channel zone, and within it many individual channels, and these channels are wide and shallow, characteristically wide and quite shallow, and they're subject to rapid shifting. They are generally unstable. We can see that in general the bars between these channels have no vegetation on them, indicating in a high flood flow they may be entirely drowned and it indicates the channels themselves rapidly erode laterally, deposit on another side and move back and forth individually. In fact the entire channel zone is also liable to shift quite abruptly. Such channels are associated with heavy sediment loads, and in particular heavy loads of coarse material that moves along the bed of the channel -- sand, gravel, and in high flood, cobbles. Often much of this material may be deposited within the reach so that the river bed is raised and aggradation commonly occurs along river channels of this type.

In the Arctic these channels are usually winter dry and so permafrost can occur at fairly shallow depths beneath such a channel. The second type, so-called braided anastomosing is illustrated on the right and the ten-gallon term, "anastomosing " is taken to refer to rivers with several channels but

M.A. Church
In Chief

1 within which the islands between the individual channels
2 are permanent or more or less permanent. What I mean
3 by "permanent" is that they persist for long enough
4 for mature vegetation to develop on them. In nature,
5 of course, if you take a long enough view of things,
6 nothing is permanent, but as opposed to the rapidly
7 developed and destroyed channel bars of the braiding
8 type, these channel islands in an anastomosing river
9 last a long time. Now there may also be sections
10 where the river braids, and there are channel bars
11 come and go quite quickly, so this is a hybrid type
12 channel. Some of the islands persist; some of them
13 come and go. These channels usually have somewhat
14 better defined individual channel ways than the braided
15 type and they're more stable than the braided channels
16 that I've referred to. Such rivers carry lesser
17 sediment load than do braiding channels, and often
18 they are not aggrading. In fact, a braided river that
19 has been aggraded and then for some reason sediment
20 supply is reduced may often change its character over
21 a period of time so it becomes an anastomosing river.
22 So we are seeing the results of reduced sediment supply
23 in a river of this type.

24 The illustration in fact is
25 a reach on the Porcupine River tributary, it's actually
26 on the Alaska side of the border but similar rivers are
27 common on the Canadian side as well. That was a good
28 illustration that I happened to have.

29 A third type is a Gravel River
30 that flows in a single channel which is well-defined.

M.A. Church
In Chief

1 These rivers, illustrated by this cross-section type,
2 are usually stable. They may actually be degrading,
3 which is to say the characteristic of the river is
4 picking up sediment and moving it out of the reach
5 so that the bottom of the river channel is being
6 lowered. Very often after this has occurred for a
7 while, the floor of the channel becomes covered with
8 a layer of large cobbles that the river cannot now
9 move. These cobbles might have appeared in the river
10 section at an earlier time when the river was more
11 powerful, more water running down it perhaps and was
12 capable of moving larger material, or the material
13 might have been put there by other agencies, perhaps
14 the river had been eroding in glacial till when it
15 encountered large cobbles in the glacial till.

16 Such a deposit of large cobbles
17 on a stream bed is called a lag deposit, since it's
18 material that is left behind when finer material is
19 eroded away, and once the floor of the river is covered
20 by these things, it usually becomes stable under normal
21 alluvial forces. The illustration on the right is a
22 reach on Babbage River on the Yukon north slope. In
23 the sub-Arctic we have rivers like Willow Lake River,
24 which is a similar well-defined single channel in
25 gravel.

26 Moving along to the second
27 major type, in the Arctic we find some large rivers that
28 characteristically have sand beds and high silt banks.
29 Looking first at the anastomosing case, which is
30 illustrated by Arctic Red River near Martin House,

M.A. Church
In Chief

1 on the right, the effect of the silt banks is to re-
2 strict the river to a narrower, deeper channel than is
3 the case in sand and gravel. Silt is cohesive, it has
4 some resistance to erosion, and so rather than eroding
5 rapidly to a wide shallow channel, the river is restric-
6 ted within silt banks and takes on a deeper, narrow
7 section. Since the banks erode reasonably slowly,
8 the channels remain well-defined and they shift only
9 slowly. The sand bed of these rivers may be subject
10 to quite rapid scour and fill during floods, however,
11 usually greater depths of scour and fill than you
12 may find on the gravel rivers we've been looking at.

13 These rivers carry a relatively
14 high load of suspended sediment, fine material that is
15 carried within the flow itself and not dragged along
16 the bed.

17 THE COMMISSIONER: Excuse me,
18 Mr. Church.

19 A Yes?

20 Q To go back, you intro-
21 duced the subject of scour there for a moment.

22 A Yes.

23 Q Do you mean ice scour?

24 A No, I mean scour due to
25 the fact that as a floodway comes down the river chan-
26 nel, water levels rise, velocities increase, and so
27 greater sheering forces are brought to bear on the bed
28 and consequently erosion of the sand on the bed occurs,
29 material is entrained in the flow and taken away.
30 I will deal with this subject again in a few minutes

M.A. Church
In Chief

1 and I will discuss ice scour at some length later on.

2 In rivers of this type when
3 the suspended sediment load is -- or a portion of it
4 is often deposited over bank, outside the main river
5 channel, and when the river channel floods the common
6 conception, I think, that most of us have of a
7 river, is of a river of this sort, it sits within its
8 banks and is normally well-behaved, but occasionally
9 large floods occur, the river gets outside its bank
10 and deposits a lot of silt all over the countryside
11 and this is the sort of thing we read about in the
12 newspapers very frequently. The reason the sediment
13 can get outside the banks in large measures is because
14 it's carried in suspension on the load, so when flow
15 outside the banks in the flood, sediment goes
16 with it, and then is deposited when the waters slow
17 down outside the banks.

18 So consequently these floods
19 and the associated deposition contribute to the building
20 up of the river's flood plain and the heightening of
21 the banks. Large rivers of this type usually contain
22 water year-around, or they are usually deeper than
23 the seasonal depth to which ice-covered^{grows} on the
24 river surface and so there will be flow
25 in the winter under the ice cover. Rivers of this
26 type may be aggrading or they may be stable, or they
27 may even be slowly degrading.

28 Single thread channels of this
29 type, such as is illustrated in section here, are similar
30 to the anastomosing channel I've just described, except

M.A. Church
In Chief

1 that they're more often stable than degrading, and
2 they're not aggrading at all. Rivers of this type
3 with single channel, usually meander more or less regul-
4 arly, and the meander shifts slowly across the river
5 flood plain. Since there is water in the channel
6 year-around, and the temperature of the water then
7 must be above the freezing point, it follows that the
8 temperature of the bed below the river channel will
9 remain above the freezing point as well and so under
10 rivers of this type we do not usually find frost at
11 shallow depths below the bed. So in permafrost a
12 cross-table of permafrost will drop sharply away under
13 the banks of the river. Now if the river is sufficiently
14 small and the permafrost is sufficiently thick then we
15 may find permafrost at some depth. These lines may
16 join.

17 If in fact the river is very
18 large, permafrost is reasonably thin, in fact there
19 may be no frost at all under the channel zone at any
20 depth.

21 I'd like to indicate several
22 special channel types that occur in Northwestern Canada.
23 The first one is rather unusual, and they are what I
24 call ^{estuarian} channels, for a reason that I will tell
25 you now.

26 Along the Mackenzie River, the
27 tributaries entering the main river usually are anomal-
28 ously wide and shallow at and near their mouths, at
29 or near Mackenzie River itself. This feature is
30 common in channels that are frequently in back-water,

M.A. Church
In Chief

1 channels that are frequently flooded from down-stream.
2 Notably tidal estuary channels where every 24 hours
3 or every 12 hours, perhaps, there's a twice-daily tide,
4 the tide rises and floods back into the river channel.
5 Then the channel becomes very wide and shallow.

6 THE COMMISSIONER: These are
7 flooded by the main stem, is that right?

8 A Yes, in this case we're
9 not dealing with a tide but we're dealing with the
10 important annual flood on the main stem of the river.
11 So a back-water develops and the channel morphologically
12 looks the same way as we frequently find in properly
13 tidal channels, and that's why I call them estuarine
14 channels, even though this is not a proper use of the
15 term "estuary".

16 Such channels are normally
17 stable. They may occur in either sand or gravel, and
18 are common along the Mackenzie, particularly on the
19 east bank tributaries which have relatively small sedi-
20 ment loads and here I have this feature illustrated
21 simply by looking at the mouth of Blackwater River, it's
22 not a good slide and I apologize but it's the only one
23 of the type I have.

24 A second type which is wide
25 and shallow is lake outlets, and there are quite a few
26 lake outlet reaches in Northwestern Canada, where there
27 are many lakes. Very often lakes spill over bedrock
28 or gravel rims, that are held in by glacial deposits,
29 perhaps, or perhaps by bedrock, and where they spill
30 over these rims the channels are wide and shallow,

M.A. Church
In Chief

1 and regulate the outflow so if the lake is of some
2 size, extreme floods are damped out downstream from
3 the lake. Usually reasonable stable river sections
4 persist for quite some distance downstream from the lake
5 outlet.

1 A third type of channel that
2 I would like to draw brief attention to now are delta
3 distributary channels, particularly the distributories
4 of Mackenzie River, ^{and} one of the small channels on the
5 Delta is illustrated on the right. These are of
6 the sand bed, silt bank type or possibly silt bank and
7 bed and they are usually stable or shift only slowly.
8 Sometimes in these channels an inner channel is found
9 to be prominent so that you will have outer banks and
10 a fairly wide channel near the surface but then a
11 narrower deep channel inside.

12 The reasons for this mor-
13 phology are not clear. One can think of at least
14 two possibilities. One, this inner channel may be
15 the result of scouring processes that occur when
16 flow occurs under ice cover in the winter. Alterna-
17 tively, near seasonal water surfaces, the banks,
18 particularly if they have got a high ice count in
19 them, may be subject to quite rapid erosion as ice
20 melts from the banks and so the banks may in fact
21 simply be eroded back an ^{unusual} distance near the
22 surface of the stream. Bank erosion processes are
23 often quite severe in such circumstances as I will illus-
24 trate in a minute.

25 I would like, just for com-
26 pleteness, to remind you that sometimes fairly major
27 rivers flow on bedrock and here we have a view of Firth
28 River to illustrate rock banks and there will be
29 bed rock at a shallow depth under that gravel fill in
30 the bed of the river at this point as well.

Small channels are very important for very often they are draining head water areas where the effects of changes in the land surface can have quite a serious effect on run off on a local scale, so that very major changes may occur in a short period of time. Types that are quite common include gravel bedded upland channels illustrated on the right. These channels are cobble lined with usually cohesive banks which may themselves be cobble lined as well, or may simply be stabilized by a thick vegetation mat along the bank. These channels are usually not alluvial, that is they are not flowing in their own sediments.

Frequently such upland channels flow on bedrock as well.

River channels in muskeg are characteristically narrow and deep, the banks are well protected by vegetation roots and such channels are stable or they shift laterally only very slowly, the bottom can be of almost any type. These channels frequently flood the surrounding terrain during spring floods as is illustrated in the view on the right.

A special channel type that occurs in permafrost country, is so-called beaded channels. These are very narrow and deep. Very often they are widest below the surface and they are turf banked and they form by thermal erosion of formally frozen ground and commonly, and as Dr. McKay very graphically illustrated this morning, they develop along lines of former ice wedges with the beads

1 of pondlike enlargements along the length of
2 the channel being initiated perhaps where a large mass
3 of ice melts out possibly where two ice wedges formally
4 intersected and so there is a great bulb of
5 ice.

6 I might say that these
7 channels are mostly pretty small and when one is
8 working around them it is often a temptation to try
9 and jump over from one side to the other, but if you
10 miss your step you can be in trouble.

11 THE COMMISSIONER: We will
12 bear that in mind.

13 A Carry a plank.

14 A final type of drainage
15 line, really, rather than channel, that I would like to
16 draw your attention, is what I call a tundra seepage.
17 This often occurs without a well-defined channel
18 in the usual sense. Water seeps through peat or
19 grasses often between higher so-called inter-sloughs
20 which are sedge or they are often heath and tundra
21 grass, vegetated, and the drainage line is identified
22 mainly by this contrast of vegetation between the
23 heathy tundra surface and the grassy and sedgy
24 seepage areas. Very often slow down slope movement
25 of the surficial material is occurring everywhere in
26 terrain of this sort. Dr. Fyles referred to such,
27 slowly soliflucting slopes this morning.

28 There is some geographical
29 pattern to the distribution of these channel types which
30 may be of at least preliminary help in further

M.A. Church
In Chief

1 hydrological work and analysis.

2 The gravel rivers carrying
3 considerable coarse sediment are found around the
4 Mackenzie Mountains here, rivers such as the Mountain
5 River, the Keel~~e~~ River and Redstone River and the Nahanni
6 River and draining the British mountains of the
7 Yukon north slope. These are areas where there is
8 considerable supply of sediment available and it is
9 this large supply of coarse material that is one
10 of the important features in determining the occurrence
11 of these wide, shallow gravel rivers.

12 By contrast, the east bank
13 tributaries of Mackenzie River draining from lowland
14 areas where precipitation is, consequently runoff is
15 smaller than the mountains, where there is no great
16 sediment supply and many of these rivers being late
17 controlled, so having less propensity to flood to
18 extreme, are generally stable, very often gravel
19 floored, but nevertheless, stable channels.

20 The sand bed silt bank channels
21 comprise the large lowland rivers, for example, the low-
22 er course of Arctic Red River, the Peel River and many
23 smaller rivers, Channels of this type are common
24 flowing through country that is underlained by the
25 lacustrine clays that Dr. Fyles pointed out this
26 morning.

27 Muskeg drainage of course
28 is widespread in lowland terrain, everywhere in your
29 study region. Non-channeled flow is common in the
30 north, particularly over frozen ground during the snow

1 melt period in the spring, and I think that it is
2 important to take account of the conditions of non-
3 channelled flow when designing structures or doing
4 any geotechnical work in the North, for change or
5 inadvertant channeling of this non-channel flow
6 may start to produce severe gullyng locally, where
7 previously the flow went merrily on its way and
8 adequately crossed the frozen ground without doing
9 any damage, so that if you inadvertantly concentrate
10 a considerable volume of this water, you may create
11 a channel where none existed before and this may or
12 may not be a nuisance.

13 As well, lakes are very
14 common in the North. In general, five types can be
15 recognized. In country underlain by permafrost where
16 the degradation of the frost limit -- the limit of
17 permently frozen ground may be occurring, thermokarst
18 lakes occur and Professor McKay discussed these
19 extensively this morning, so I will not say anything
20 more about them, but similarly in areas that were
21 formally occupied by glacial ice and in particular
22 where the ice may become buried in site, rather than
23 melting on the surface, if the ice became buried under
24 its own glacial debris, when the ice subsequently
25 finally did melt, the melting of isolated blocks of
26 ice might cause local subsidence of the surface and
27 then a hole is left called a kettle hole, sometimes
28 fills up with water and becomes a pond or a lake.
29 The hydrology of thermokarst ponds and kettle holes is
30 apt to be similar. In particular many of them may not

M.A. Church
In chief

1 have external drainage, that is to say, they may
2 just be self-contained, they receive enough precip-
3 itation and run off from local snow melt to maintain
4 themselves against summer evaporation losses and in
5 places such as this, inadvertant activity around
6 these ponds can easily cause a major change in the
7 water balance of these small lakes.

8 Larger lakes, include those
9 that are held up by dams of glacial material, such
10 as morraines, till and the very biggest lakes of
11 all that are rock rimmed, they are held in by low-
12 lying areas in the bed rock geology and all of the
13 bigger lakes in the Mackenzie region are of one
14 of these two types.

15 The lakes in river deltas
16 are another type, principally the Mackenzie River
17 Delta in your study region, -- these are formed as
18 a result of river sedimentation processes. These
19 lakes form in all deltas when channels shift or when
20 they extend at the Delta front and an area of open
21 water may be cut off in the course of this activity.

22 However, these lakes seem to
23 persist for particularly long periods of time on
24 Northern deltas, in the normal course of things
25 sedimentation from flood waters which overspill into
26 these lakes periodically, very rapidly fill these
27 lakes up and disappear from the landscape and so
28 the delta surface becomes generally dry ground, but
29 in the North this does not seem to occur. I
30 think that there are two reasons for this.

M.A. Church
In Chief

1 First, frost aggradation into
2 sediment deposited along the channels often leads
3 to the development of high, quite stable channel
4 banks, so that subsequently flood waters do not get into
5 these lakes nearly as frequently as they might do
6 where channel banks remain low. Consequently they
7 become isolated from frequent receipts of sediment
8 so that they do not fill in very quickly.

9 Secondly, much of the lake
10 in filling that occurs on delta surfaces appears to
11 be due to the accumulation of organic debris from
12 vegetation that begins to grow around the lake.
13 Reduced growth rates in the far North effectively
14 slow down this process and so once again the lakes
15 persist for a long time.

16 This feature has not been
17 studied closely to my knowledge, so to demonstrate fur-
18 ^{that}ther to you/the persistence of lakes in the North is
19 not a peculiar feature of just the Mackenzie Delta
20 whose lakes are famous, I have on the right a slide
21 which is a picture of the Dicyoc(?) Delta in Northern
22 Sweden and shows similarly a large amount of open water,
23 although this is properly a sub-arctic delta, this is
24 the lake, this is the river -- this Dicyoc's draining
25 into -- there is a great deal of open water on the
26 surface here, even in the sub-arctic -- although you can
27 see vegetation growing under these lakes.

M.A. Church
In Chief

1 Then again, if we look at the
2 Peace-Athabasca Delta farther south in Canada, and not
3 too many miles south of here, we see again the same
4 inter-channel depressions that are former lakes and
5 that
6 some of them persist, and/we have on Mackenzie Delta
7 and these are filling in largely by plant succession
8 and build-up of organic debris. This appears to occur
9 much more quickly in these areas farther south.

10 If all this is true one would
11 accept the same -- one would expect, I'm sorry, the
12 same phenomenon on lake persistence to occur on river
13 flood plains where the shift of a river channel might
14 leave some open water, and this view of a meander bend
15 on Porcupine River confirms that this does in fact
16 occur in the sub-Arctic. The river channel has formerly
17 flowed in each of these areas over here, due to normal
18 erosion and depositional processes, the river has
19 sifted away from these places so it is now over here,
20 but instead of these lakes filling in quite rapidly
21 with over-bank sediment, they persisted for quite a long
22 time.

23 The data of sediment transport
24 in rivers of Northwestern Canada is restricted to
25 recently instituted suspended sediment transport
26 observations, and some observations of material in
27 solution in a few major rivers. I pointed out briefly
28 the locations, mainly along the Mackenzie main stem
29 where these observations have been instituted. But
30 we really have very little material of a quantitative
nature on sediment transport in these rivers, and so we

M.A. Church
In Chief

really do not have a great deal to go on in the way of direct information in making calculations of sediment transport, deposition and erosion rates. River bed scour and fill during floods in northern rivers proceeds in much the same way as it does in rivers anywhere else, and so ^{geomorphological} and engineering experience from rivers in other regions will be of use in assessing the scour and deposition conditions due to normal river processes that can be expected in rivers in the north. This is true unless either the river bed is frozen and sometimes may occur, particularly in the winter dry gravel rivers of the Arctic, that the important spring melt-water flood comes down the river when the bed that has been exposed all winter is still frozen, in which case it may resist scour which may otherwise occur. Or when there is ice in the channel, which is capable of modifying flow patterns, or causing direct abrasion on the bed; and in this case the ice may cause peculiar scour features that I will illustrate later on.

In gravel rivers in the Arctic north slope in particular, this view is from below-river, the spring freshet may pass over a gravel bar of this sort whilst the bar is still frozen, and so consequently no damage may occur, where otherwise it may.

River bank stability as opposed to river bed stability is a subject which has some peculiar features for northern rivers that is related to the conditions of the northern rivers.

M.A. Church
In Chief

1 I have put down here a typology of bank types that can
2 be found, some of them peculiar to the north, some of
3 them not so much. On the left, the erosional types;
4 on the right here, stable bank types; and depositional
5 banks below.

6 The first type, the thaw
7 niche, which is illustrated on the right, is a peculiarly
8 northern feature. This develops where river waters
9 thaw frozen sediment, usually this is fines with high
10 ice content, though I've seen the same feature develop
11 in frozen gravels as well, and as the thaw occurs at
12 the water line, erosion occurs at the water line.
13 The frozen bank above the water line is left overhanging
14 whilst the niche is eroded back until ultimately the
15 beam strength of this unsupported bank is exceeded,
16 whereupon the whole unsupported bank will slump in the
17 river and this section of the bank has done that quite
18 recently.

19 Niche development may occur
20 quite rapidly. Erosion rates of several feet a day
21 during spring flood levels are not uncommon, particularly
22 when the water is quite warm, as may be the case if it's
23 flowing down north, in a river that is flowing to the
24 north ^{from} regions to the south where conditions may be
25 considerably ameliorated.

26 In very extreme cases, niches
27 can grow to nearly 10 meters in depth, that would be
28 an extreme case. Usually the bank fails before that.

29 Vertical banks, high vertical
30 banks are not uncommon in fine sediments along rivers

M.A. Church
In Chief

1 anywhere, fine sediments -- silts and clays have a
2 cohesion of their own and they're able to stand up in
3 section. In frozen ground they may stand up to consid-
4 erable height and even develop notable overhangs. As
5 melt proceeds on this vertical face, however, the mater-
6 ial is sloughed off and then it is carried away by
7 the river at the base, the bank remains vertical and
8 continues to melt and move back, and erosion proceeds
9 in this way for a long time indeed.

10 If the river does not move
11 material from the base, then it may pile up on the face
12 and when a sufficient amount of material has piled up
13 the bank may stabilize for a while until perhaps a major
14 flood moves this debris pile and restores a vertical
15 bank and begins to erode the base again.

16 Amongst protected or stable
17 slopes, lag cobbles, which we've looked at before,
18 that's stones too large for the river to move, and
19 pavements of cobbles that have been scoured into a
20 tight cobblestone pattern by ice movement, ice abrasion
21 over them, are common on northern rivers. As well,
22 vegetation roots often form a rip-rap which effective-
23 ly stabilizes a bank, although the washing out of fines
24 from under those roots might eventually cause the
25 vegetated material to be torn away and the bank to
26 erode backwards over a long period of time.

27 THE COMMISSIONER: What do
28 you mean by "fines"?

29 A By "fine material" I mean
30 silt or clay. I'm sorry.

M.A. Church
In Chief

Depositional bank types include slip-off slopes of meandering river such as this, this is a view of Little Slave River which is regularly meandering, and as this meandering proceeds on the outside banks here where the current is usually quite strong, when the water goes around the corner, erosion occurs on the inside bank; where there is usually slack water, sediment is commonly deposited and builds up what's called a slip-off slope, the river is slipping away from this bank, a depositional bank frequently occurs in such circumstances.

Secondly, channel side bars such as illustrated on the right, constitute another depositional slope type, this type. The difference between these two types, although they're superficially similar, they are both formed by the deposition of fine materials along the river bank, the difference is that since the river is shifting persistently on a meander bend, this slip-off slope deposit (also called a point bar deposit) tends to remain for a long time, whereas channel side bars which may form in quiet water along the side of a river, are apt to be scoured out quite frequently when a major flood comes through and fills the channels to a higher level. These channel side bars, although they're depositional, are not likely to be stable over a long period.

Mechanisms for river bank erosion are shown here, and I've drawn these mechanisms up in such a way that they conform with the mechanisms of general slope instability that have been found in

M.A. Church
In Chief

1 the Mackenzie River region by other investigators.

2 The major difference between slope instability at
3 river banks and slope instability elsewhere in the
4 terrain is that if the river persistently removes the
5 sediment from the base of the bank slope, then the
6 stability may persist for a long time, and Professor
7 McKay mentioned this fact this morning.

8 First of all, active layer
9 detachment, simple sloughing of material off the
10 surface where the frozen zone moves back from the
11 surface due to seasonal thaw processes, may occur along
12 vertical or near-vertical banks. We can call this
13 an active layer detachment.

14 Secondly, retrogressive
15 thaw slides or flows commonly occur, particularly where
16 there is massive ice under the surface which melts out
17 with a lot of water present, a mud slurry is produced
18 which may flow down quite a small slope and so such
19 a slide or flow may remain active for a long, long
20 time, particularly if material is removed from the
21 bottom of the flowing section of the slope.

22 Thirdly, rotational slumps,
23 the bottom illustration on the right-hand side, may
24 occur frequently along river banks, particularly where
25 tension cracks can occur back from the bank as support
26 for this ground is removed from the front by prior
27 river erosion. This is particularly common in terrain
28 where ice wedges are present; where the ice wedge line
29 provides a point where tension cracks can easily
30 develop, the ground may be weak. In addition, slumps

M.A. Church
In C hief

1 are of course associated with the failure of thaw
2 niches and in fact this illustration follows the
3 failure of a thaw niche.

M.A. Church
In Chief

Turning from short-term erosional and depositional conditions to those of a long term, I'd like to point out that long-term sedimentation in northern rivers proceeds much as elsewhere so again experience from river studies elsewhere is important in understanding northern rivers in this respect. In the gravel bed-load transporting rivers which develop ^{their} deposits by rapid deposition of a lot of material in the channel zone during a flood and then lateral shifting of the channel-way around that sediment pile, it often occurs that the entire channel zone will be periodically re-located to get around sediment deposits. This is known as a bulge when the entire channel zone shifts, and is not uncommon on rapidly aggrading gravel rivers. The illustration on the right of the Firth river on its delta sand near the Yukon north coast shows an old channel zone in the foreground here and behind the present channel zone which is flowing locally here in an entirely different way down the sand, so at some point in the past the entire channel zone has shifted its course, presumably as the result of local depositional processes in the former channel way.

As I pointed out, silt-carrying rivers deposit much of their sediment over-bank from suspension, and thereby they build up their flood plain surfaces vertically whilst the river itself may remain within the same channel zone for long periods of time. This is seen in this cut-bank here ^{and} this illustration ^{is} similar to one that Professor McKay showed

M.A. Church
In Chief

1 this morning for a different purpose, however, in this
2 case since these trees commenced to grow, a good deal
3 of sediment has been deposited over the bank and now
4 is revealed by erosion of that river bank.

5 Again, as Dr. McKay mentioned
6 this morning, these fine sediments are often susceptible
7 to the development of ice when permafrost ^{aggrades} into
8 them. Along these channels in the north, levies develop
9 near the channel bank. A levy is a ridge along the
10 channel, so that the land farther back from the channel
11 will be lower than the bank itself. This results from
12 the fact that when the river flows out of its channel
13 the water ^{immediately} encounters vegetation, slows down and deposits
14 sediment and much of the sediment is deposited very
15 close to the river itself, so the bank builds up quite
16 high.

17 In the north these sediments
18 may build up and then persist as especially prominent
19 features, possibly protected by becoming frozen. In
20 the view on the right of Mackenzie Delta, virtually
21 all the land is river-levy.

22 Ice action is important in
23 northern rivers. When ice forms in the autumn it
24 either develops as a continuous cover of skim ice,
25 thin ice which then thickens into sheet ice, and
26 this occurs provided the water flows quietly and the
27 surface is smooth. By flowing quietly I generally
28 mean the flow velocity is less than one foot per second.
29 In such circumstances sheet ice develops on the surface
30 and becomes stable and very often remains that way for

M.A. Church
In Chief

1 the winter. In rougher flow, generally flows of
2 greater than one foot per second velocity, instead of
3 skim ice and then sheet ice developing, what may hap-
4 pen -- and this diagram shows skim sheet ice and a
5 continuous ice cover developing on this side -- it
6 may get broken up before it becomes stable, in rougher
7 flow platelets and spicuals of ice form in the flowing
8 water, rather ^{than a} continuous cover forming individual
9 plates and spicuals of ice develop at the surface and
10 also growing on the channel bed. The ice that develops
11 in flow, which is known as frazil ice, continues to
12 run down the river with the flow. If it develops quite
13 extensively, then individual plates and spicuals of
14 ice will come together and form frazil slush, and these
15 will continue to run down-river with the flow until
16 they meet some impediment. This impediment might be a
17 section of the river where a stabilized cover has
18 developed where the flow is quieter there. When this
19 occurs, the frazil piles up against this impediment
20 and the frazil slush pile progresses upstream as
21 more and more ice piles in. Now this may freeze and
22 stabilize itself.

23 In some occasions, however,
24 the flow is strong enough the frazilize ^{ice} may be drawn
25 under the unstabilized cover and then it may stick
26 under the ice cover somewhere farther downstream, and
27 develop into what's known as a hanging ice dam. The
28 significance of this feature is that under the hanging
29 ice dam the area available for water flow is restricted.
30 In order to overcome this, water levels may rise up-

M.A. Church
In Chief

1 stream and force water under this dam at higher velo-
2 cities than previously, and consequently local scour
3 may develop on the bed of the river under the location
4 of these frazil-ice dams which I show developing here.

5 This process of development of
6 jamming of frazil ice and progression and hanging ice
7 dam development may form, water pressures against the
8 dam may become so great that ultimately the whole thing
9 breaks up, the ice continues to run down the river and
10 then the sequence may repeat again. Or alternately, a
11 stabilized cover may form and the situation may
12 stabilize.

13 More important than these
14 winter ice runs and jams are events that may occur
15 in the spring. In the spring stabilized cover on the
16 rivers is usually first broken up by rising water
17 levels as snow melt water finds its way into the
18 river channels. This produces an upward pressure on
19 the ice cover, and the ice cover often breaks off
20 from the shores at shore base, some ice remains attached
21 to the shore but the ice breaks and transverse breaks
22 also occur across the river channel.

23 After this, if the water
24 rises quickly and brings considerable pressure to bear
25 massive ice movement may begin once the ice has been
26 broken loose from the banks. The ice may move down the
27 river breaking up into pans and continue to move
28 until a constriction is reached, usually a narrowing
29 of the channel or perhaps a sharp bend in the channel,
30 where a major jam may develop. The ice wreckage may

M.A. Church
In Chief

1 start to pile up here because it can't all get
2 through the constricted section of channel and then
3 a major jam may occur. In general, the rapid rise
4 of high water levels in the spring will produce
5 relatively rapid ice clearance, but with the possibility
6 for very large jams to occur, since the ice is moving
7 down the river quickly. If there's a slow rise in
8 water levels, and a moderate water level reached, the
9 ice may persist much longer on the river but there
10 will be many small jams and the chances of a really
11 major jam developing somewhere are smaller.

12 Now the speed with which water
13 levels rise, of course, will depend on weather condi-
14 tions, the rapidity of snow melt and so on. So
15 whether or not major jams develop is a function of
16 the weather sequence in any one year.

17 This graph which plots ice
18 thickness on this axis and the number of days neces-
19 sary to clear the ice on this axis and shows by dif-
20 ferent colored symbols, different types of ice cover,
21 illustrates that in Northern Canada it takes from a
22 few days to greater than a month for breakup to
23 completely occur. On the rivers, which are the red
24 symbols, with few exceptions breakup occurs within
25 about three weeks; and if currents, river currents
26 are very important, the breakup can occur in only a
27 few days. When breakup occurs in circumstances like
28 this, then the possibility exists for massive jamming
29 to occur. When breakup takes considerably longer
30 to be completed, ice is not moving as quickly or as

M.A. Church
In Chief

frequently, and major jams are not so apt to occur. None of these statements can be made absolute for peculiar conditions in any one year might produce a really major jam, as a result of chance circumstances.

The time of year when breakup occurs is, in the study region, generally late May. It's interesting that along the Mackenzie River from Fort Simpson to near Fort Good Hope, breakup is practically synchronous. This is the result of the influence of the major snow melt flood coming out of Liard River both upstream from Fort Simpson and downstream from Good Hope, it's usual for breakup on Mackenzie River to be later than the time when breakup occurs on this section of the river. But generally between about May 15th and May 30th, breakup occurs almost everywhere in the study region of interest, out in the Mackenzie Delta and Yukon coast; the first week in June is a useful more/mean date to think about.

When ice runs in wide shallow gravel rivers, those that are often empty during the winter -- and ice doesn't always run in these rivers but it may remain anchored to the bed throughout the spring snow melt flood -- but when it does run it may abraid the bed directly as it moves down the wide and shallow channels, or the ice may run up on the river bars, such as the bar I illustrated a while ago. If the material on the bars is unfrozen, it may be abraided as is indicated by the very irregular pattern of material on this channel bar in Babbage River on the Yukon north slope, and where individual blocks of ice

M.A. Church
In Chief

1 come to rest, patterns of scour around the ice blocks
2 and sediment deposition in the lee of them, may consider-
3 ably disturb the bar surface. In sum, the absolute
4 depths of scour are not ^{usually} very deep, but an irregular
5 pattern may occur. It may occur in a different way from
6 year to year and over a period of years it may lead to
7 the destruction of a river bar deposit that may appear
8 in ^{the} short term to be reasonably stable.

1 On rivers that contain a
2 surface ice cover and flow under the ice cover through
3 the winter, ice wreckage which moves down stream on
4 the rising water levels in the spring may pile up to
5 produce major dams as illustrated -- major jams, I
6 am sorry -- as illustrated by the ^{mouth of Willow} Lake River
7 here and by the Mackenzie River near Norman Wells.
8 Both of these photos were taken on May 14, 1973.

9 In situations such as those,
10 the ice may scour the bed directly where it grounds
11 under the bed and it may push debris to high levels on
12 the banks as is illustrated in these two pictures,
13 both of them along the Mackenzie River. Major ice
14 jam sites are at points where the river narrows or
15 turns sharply and so jams tend to recur at the
16 same sites from year to year. For example, the major
17 locations of recurrent ice jamming on the Mackenzie
18 River are illustrated on this slide, so we can identify
19 those points where ice jams are most likely to
20 recur and threaten structures on the river bank.

21 Where flows must pass under
22 a major jam or under a hanging ice dam in winter,
23 the restricted passage may produce scour on the
24 bed. The four crosssections and these are sonar tracks,
25 illustrated on the right are from the Mackenzie River
26 just downstream from the confluence with Arctic Red
27 River, just down here and on two of these the
28 exaggerated depth of the inner channel may indicate
29 the effect of scouring under ice wreckage. I cannot
30 be sure of this for the observations being directly

Similarly, if closure occurs both upstream and downstream, the water left in the unfrozen gravels between these two points, as freezing continues, will come under increasing pressure,

1 for
2 /ice being less dense than water takes up more volume
3 and so the volume available to the remaining water will
4 be steadily more restricted. In either case pressure
5 develops and finally the frozen cover may be ruptured
6 by this pressure and water moves to the surface and
7 freezes.

8 Icings at springs of course
9 may occur at the surface at or downstream from the
10 site of resurgence of the spring and in some places
11 in the mountains of Northwestern Canada, thermal
12 springs continue to flow through the winter and icings
13 may develop near them, and finally small icings may
14 occur near the base of slopes where non-channel
15 seepage comes to the surface, but these are usually
16 minor.

17 In this view, also of the
18 Firth Delta icing, spring runoffs have flowed over
19 the icing and has deposited sediment on it. This
20 illustrates the salutary effect of icing, that it
21 may protect a section of the river bed from possible
22 scour during floods. To illustrate that these features
23 are quite common, particularly on the gravel rivers
24 of the northslope, here is an icing on Trail River,
25 some miles to the east of Firth River.

26 Icings have two major effects
27 on river stability. First, although they usually
28 form on the surface, it is possible in a closed system
29 icing, that is where there has been frost closure
30 both upstream and downstream for the water to be trapped
and frozen below the river bed and for the frozen

1 river bed, above the unfrozen gravel and water, to be
2 sufficiently strong that rupture does not occur at a
3 specific site. When this occurs the whole river bed
4 may be heaved upward and this is illustrated in the
5 slide on the right. In the following summer of course,
6 water flows down the channel, past this heaved site,
7 begins to erode it, largely thermal erosion occurs, and
8 as the ice melts the sections of heaved channel bed
9 fall off into the river and are moved some distance
10 down stream.

11 The particular importance
12 of this feature which, so far as I know, has not been
13 stressed anywhere in geotechnical literature previously,
14 is that a channel bed which is stable, under normal
15 river processes, a channel bed consisting of lag
16 cobbles, for example, which we described awhile ago
17 may be disturbed, completely derranged, due to a
18 process such as this and so the bed may become
19 unstable in the vicinity of icings of this sort that
20 actually grow under the river bed.

21 The second effect of icings
22 on river stability is that some times they grow in
23 the winter and fill up the entire channel and these
24 are two views of Canyon Creek, the small creek near
25 Norman Wells, one in the autumn and the other view in
26 the following spring. In the winter an icing is
27 developed which substantially fills the channel, it
28 does not melt out before the spring flood occurs and so
29 the spring flood pours over the icing and may thereby
30 get right out of the river channel. Once outside

M.A. Church
In Chief

1 the river channel, it may go almost anywhere down
2 valley and in particular this may be a cause of
3 evulsion of the river, movement outside its channel
4 and rerouting of the river channel and in particular
5 this may threaten structures that are built at
6 or near the banks of the rivers downstream, if they
7 are exposed to this sort of action.

8 As a final aspect of Northern
9 Rivers, it is interesting to ask about^{the} long term
10 behaviour of the river. At the end of the last
11 glacial period which Dr. Fyles introduced this
12 morning, the abundance of sediment that is available
13 to the rivers around the margins of retreating ice
14 sheets, led to large scale sediment transport and
15 aggradation of river beds, producing valley fills of
16 sediment as seen on this view of Bow River, on the left
17 is gravel sill in the river valley is produced largely
18 early, in the early period after the last glaciation,
19 some seven to ten thousand years ago and on the
20 right, away from valleys, large sheets of outwashed
21 material were deposited on the coastal plains here on
22 the Yukon north slope.

23 Similarly, features such as
24 these alluvial fans of sediment here in front of the
25 Richardson Mountains near Aklavik were largely built
26 up during this period early after the end of the
27 last glacial episode. Since that time increased
28 vegetation cover, the exhaustion of unusual exposed,
29 unconsolidated sedimentary -- sediment supplies,
30 and reduced run off with the disappearance of the

1 glaciers have greatly reduced the rate of sediment
2 movement and this is ended general aggradation in
3 the rivers of this region.

4 The rivers have responded to
5 this change in the conditions of sediment supply and
6 runoff by becoming stable or by degrading slightly.
7 This view of M alcolm River on its fan, on the
8 Yukon north slope, shows several terraces along the
9 edge of the channel, here are several terrace levels.
10 They are low terraces, but terraces they are and this
11 indicates that the channel has degraded slightly into
12 its own sediment deposits. Usually in gravel channels
13 of this sort after slight degradation, the channel
14 bed becomes floored by lag cobbles moved during the
15 early period of aggradation but not movable during
16 the subsequent period of reduced river flows and then
17 the channel stabilizes.

18 Further evidences of this
19 change in the long term sedimentary environment are
20 evident on the coastal deltas on the Yukon north
21 slope, these deltas were actively built out into the
22 sea during the early post glacial period, but now
23 sediment delivery to these deltas is not sufficient
24 to prevent erosion and trimming back of the deltas
25 by the sea and so we see land areas on the distal
26 portions of these deltas being reclaimed by the sea
27 through processes of coastal erosion.

28 In summary, many of the rivers
29 today are stable and over long periods of time, prob-
30 ably to be judged in centuries or perhaps even millenia

M.A. Church
In Chief

1 -- they may be degrading significantly. Only
2 locally where there are unusual sediment supply condi-
3 tions upstream is considerable aggradation to be found.
4 In small watersheds where changes in surface vegeta-
5 tion particularly fire, or perhaps the result of large
6 scale geotechnical activities, are found, such a
7 sediment supply may be provided by the surface sediment
8 becoming bare and exposed to the erosive effects
9 of running water.

M.A. Church
In Chief

1 Larger rivers, it's not likely
2 that such an unusual sediment supply will affect the
3 stability of the entire length of the channel at any one
4 time. In the Mackenzie and the British Mountains there
5 is still considerable sediment being delivered to some
6 rivers as a result of erosive processes in the high
7 barren headwaters of these water sheds, and these are
8 the places where most sediment movements are occurring
9 under natural circumstances today.

10 In closing, I should like to
11 remind everyone once again that much of what I've said
12 amounts to impressions, and reconnaissance observations.
13 As in many other things in the north, we have relatively
14 few records of data that are long enough to be signif-
15 icant in interpreting what goes on. I think this
16 makes it particularly important to deduce properly
17 what we can say about the hydrology and river processes
18 from what we can see of the appearance of the river
19 channels, and other features associated with water
20 in the north. That is why I've emphasized the morphology
21 of the rivers and their sediment deposits in this
22 discussion, and I hope my discussion has clarified some
23 of these points.

24 THE COMMISSIONER: Thank you
25 very much, Mr. Church. You've been most helpful.

26 (WITNESS ASIDE)

27 MR. SCOTT: Mr. Commissioner,
28 I should point out to you and the other counsel present
29 that we are making efforts to obtain copies of all the
30 slides or alternatively photographs from the slides

1 that have been used today and will be used on other
2 days, and in due course I would propose to file them
3 as exhibits so that the evidence you've heard today
4 will be meaningful with reference to them, and when
5 we are able to do that I will notify you and the other
6 parties.

7 I suggest, sir, if there is
8 nothing further to be done today that we should adjourn
9 until nine o'clock tomorrow morning.

10 THE COMMISSIONER: We'll
11 adjourn then until nine o'clock sharp tomorrow
12 morning.
